Chapter 1

Introduction

1.1 What Is LYX?

LYX is a program that provides a more modern approach to writing documents with a computer, an approach that breaks with the obsolete tradition of the “typewriter concept.” It is designed for authors who want professional output quickly with a minimum of effort without becoming specialists in typesetting. Compared to common word processors, LYX will increase productivity a lot, since the job of typesetting is done mostly by the computer, not the author. With LYX, the author can concentrate on the contents of her writing, since the computer takes care of the look.

Technically this is done by combining the comfortable interface of a word processor with the high quality of a real typesetting system. LYX uses the most popular and, in our opinion, best typesetting system available: L^AT_EX. L^AT_EX is used for a wide range of documents, especially in science. For example, it’s difficult to find a mathematics or computer science book that is not done with L^AT_EX. So, some people claim that its main purpose is mathematical typesetting. This isn’t true. L^AT_EX is equally good for writing letters, articles, books, or any other kind of document, and does so much better than common word processors. What prevents some people from using this powerful, free typesetting system, one that is available for almost every computer system, is its difficult usage. With plain L^AT_EX, you need to enter a series of typesetting commands into the text in order to produce your document. As a result, you get no visual feedback until you feed your document to the L^AT_EX program. It’s also difficult to read these documents

before they have been printed. So, online editing isn't very easy. This is where LyX enters the game.

LyX provides an “almost-WYSIWYG” view of the document. “Almost” means that the line- and page-breaks are not displayed exactly as they will appear in the printed document. However, that's not really necessary, since LyX uses a separate typesetter program [here, L^AT_EX] to perform the final formatting of your text. While LyX contains everything it needs to be a comfortable user interface, the typesetting program contains everything necessary to format text, and do so very, very well. There's no need to reinvent the wheel, after all. Besides, computers are best at following a set of rules, and doing so repeatedly and *consistently*. Why should you do extra work remembering which subsubsection in which section in which chapter you're in, what numbering scheme you're using, how big the different headings are, what font you used for the different types of headings, and so on, and so on, and so on, when a computer can do all of that for you? The answer is simple: you shouldn't, and with LyX, you don't have to. So, line- and page-breaks aren't your problem anymore. Remembering which number to use for the next subsection isn't your problem anymore. Recalling what font you used for all of your section headings isn't your problem anymore. With LyX, you simply choose a so-called “paragraph environment.” That's it. You're done.

This gives you far more power than you may think. No longer do you need to scroll through a 75 page document, changing all of the section numbers because you deleted an old section. You could even pick a section, heading and all, up out of one document and drop it in a new one. LyX does the renumbering for you, adds the section to the Table of Contents, and more! Because you tell LyX [and L^AT_EX] what *kind* of document you're editing and what *type* of paragraph this-or-that text is, the computer can typeset it accordingly. Cut some paragraphs from an old document [say, an article] and paste them in a completely different one, [say, a letter] and LyX does the rest. Of course you can also still do some low-level formatting for fine-tuning. However, the proper way with LyX is to tell the computer what the text *is*, not what it should look like. So, we like to say that LyX gives you WYSIWYM editing [What You See Is What You Mean].

Some people might be tempted to call LyX a “frontend to L^AT_EX.” This isn't quite fair. LyX performs some typesetting internally to generate the correct look on the screen. Furthermore, LyX has some extensions to L^AT_EX specially designed to work with the WYSIWYM-concept. So, it's actually better to call LyX a *High Level Wordprocessor* that uses L^AT_EX as its backend.

1.2 About This Document

If you haven't read the "*Introduction to LyX*" [the file `Intro.lyx`], you need to. Yes, we mean now.

The "*Introduction to LyX*" describes several things, most importantly, the format of all of the manuals. If you don't read it, you'll have a bear of a time navigating this manual. You might also be better served looking in one of the other manuals instead of this one. "*Introduction*" describes that, too.

A full list of credits, containing of the LyX Documentation Project member, appears at the end of this file.

1.3 Getting Started

1.3.1 Invoking LyX

Similar to other Linux [and other brands of Unix] programs, you start LyX by simply typing `lyx` at the command line. You can, of course, include several command-line options, including file names. We're not going to repeat all of the command-line options here, since we've already done that in the `man` pages for LyX. Check there for more info.

There are one or two things we'd like to comment on:

- If you include more than one file name on the command line, LyX will load them all, though it won't display them all simultaneously. More on that in a bit.
- Many of you X-perts out there will try, in vain, to use the `-geometry` option or its cousin, which has the form: `-80x24+5+5`. It won't work. This is a toolkit problem, which the developers are addressing [by ditching the old toolkit]. For now, there is a temporary workaround via the options `-height` and `-width`. There are no positioning options or X-resources, however.

1.3.2 How LyX Looks

1.3.2.1 The Main Window

Like most applications, LyX has the familiar menu bar across the top of its window. Below it is a toolbar with a pulldown box and various buttons.

There is, of course, a vertical scrollbar and a main work area for editing documents. At the bottom of the window is a small window containing a single line of text. This is the *minibuffer* [a term which we've swiped, lock, stock, and barrel, from GNU Emacs]. It not only displays status information, but takes input, as well.

Note that there is no horizontal scroll bar. This is not a bug or an oversight, but intentional. When you read a book, you expect the end of a line to wrap around to the next line. Text overflows onto new pages in a vertical fashion, hence the need for only a vertical scrollbar.

There are three cases where you might want a horizontal scrollbar. The first case is large figures, displayed WYSIWYG. This, however, is due to a flaw in the routine that displays graphics on the LyX screen in a WYSIWYG fashion; it should rescale the graphics to fit in the window, just as you'd need to rescale a graphics to fit on a page. The second and third cases are tables and equations which are wider than the LyX window. That is indeed a problem, one which will be resolved in a future version of LyX.

1.3.2.2 Popups

Ever heard of a “dialog box?” We LyXers like to call them popups windows, or popups for short. Almost all of the LyX popups have three basic buttons: **OK**, **Apply**, and **Cancel**. The first and last ones are self-explanatory. The **Apply** button works similarly to the **OK** button, in that it activates whatever changes you made in the popup; however, it doesn’t close the popup, like **OK** does. The three buttons also have shortcut keys:

- **OK** is bound to the **Return** key, as in most programs
- **Apply** is bound to **M-a** [as you might expect]
- **Cancel** is bound to the **Esc** key.

There are some popups that have different buttons. Not to worry, they’re typically self-explanatory. We just wanted to document somewhere what that **Apply** does.

1.3.3 HELP!

First, the bad news: the help system is not as thorough or idiot-proof as in many commercial applications. Patience. We’re working on it.

Now the good news: the help system consists of the LyX manuals. You can read *all* of the manuals from inside LyX. Just select Documentation from the Help menu. LyX opens a file browser that points to the directory containing all of the documentation. You can then load any of the manuals just as you would any other LyX document.

While we're at it, we'd like to make a comment about the manuals. They're not idiot-proof, not in the least. Here's what one of our authors, JOHN WEISS, once said about manuals:

I hate manuals.

Yes, we've all dealt with the terse, poorly-translated, or cryptic manuals. They are aggravating. I find, however, that the overly simplified ones are even more aggravating. First, they spend about half their time carefully explaining to the user how to operate a mouse, what a menu is, et cetera, et cetera, ad nau-seum. Please, if someone doesn't know how to use their own computer, or a GUI, then they should sit down and learn *before* they start up a major piece of software.

Second, what information they do provide seems to assume that the user is stupid. Utter nonsense! Most users, in my experience, are some combination of clueless and intimidated, not stupid. Besides, if someone is truly slow on the uptake, they need help that a manual for a piece of computer software can't give.

Editor's Note: With this in mind, I've instructed all of the other authors to avoid patronizing you, the reader, and to be more pedagogical than pedantic. As for those who are too lazy to read and understand the manuals — well, as we say here in America, there's no such thing as a free lunch. - jw

1.4 The LyX Interface

1.4.1 Basic File Operations

Under the File menu are the 6 basic operations for any word processor:

- New
- Open

- Close
- Save
- Save As
- Quit

They all do pretty much the same thing as in other word processors, with a few minor differences. The File->New command not only prompts you for a name for the new file, but also prompts you for a template to use. Selecting a template will automatically set certain layout features for the document, features you would otherwise need to change manually. They can be of use for certain classes, especially those for writing letters [see sec. 3.1.2] [*Editor's Note: This template stuff, and how it operates, may change in the near future.- jw*]

Note: There is no “default file” or document named “Untitled” or “scratch.” Unless you tell LyX to open a file or create a new one, that big, blank space is just that — a big, blank space.

The second matter of note concerns the commands File->Close and File->Quit. They both feature a “nag box” to save us all from our own stupidity. That is, if you try to close a file with changes [or quit LyX], you’ll be informed that there are unsaved files.

Lastly, you shouldn’t try to quit LyX by killing the X-window [i.e. double-clicking the upper left corner]. LyX brutally and immediately dies, taking any unsaved files with it and leaving temporary files littered all about. This is indeed a bug, and we’re working on it.

1.4.2 Basic Editing Features

Like most modern word processors, LyX can perform cut and paste operations on blocks of text, can move by character, word, or screenful of text, and can delete whole words as well as individual characters. The next four sections cover the basic LyX editing features and how to access them. We’ll start with cut and paste.

As you might expect, the Edit menu has the cut and paste commands, along with various other editing features. Some of these are special and covered in later sections, such as the Floats submenu. The basic ones are:

- Cut
- Copy
- Paste
- Find & Replace

The first three are self-explanatory. One thing to note: whenever you delete a block of text that you've selected, it's automatically placed in the clipboard. That is, the Delete and Backspace keys also functions as the Cut command. Also, if you've selected text, be careful. If you hit a key, LyX will completely delete the selected text and replace it with what you just typed. You'll have to do an Undo to get back the lost text.

The Edit->Find & Replace item opens the Find & Replace popup. LyX does its find and replace work a little bit differently than certain commercial programs. Obviously, the text you want to find goes in the Find box. The two arrow buttons search backward and forward, respectively [it's obvious which does which]. Once you've found a word or expression, LyX selects it. Hitting the Replace button replaces the selected text with the contents of the Replace with box.

Let's state that again: you can't do a replace unless you've done a find first.

To repeat a replace, click the arrow key to find the next/previous word, then hit the Replace button. There is no operation to do a "replace all". [At least not yet...]

1.4.3 Undo and Redo

If you make a mistake, you can easily recover from it. LyX has an infinite-capacity undo/redo buffer. Select Edit->Undo to undo some mistake. If you accidentally undo too much, use Edit->Redo to "undo the undo."

You can't use Redo beyond the most recent change. Likewise, you can't Undo beyond the first change you made after opening the file. If you try to do either, LyX issues a warning message in the minibuffer.

The Undo and Redo work on almost everything in LyX. They have some quirks, too. They won't Undo or Redo text character by character, but by blocks of text. That can take some getting used to; you'll have to play with Undo and Redo to get a feel for just how much they'll undo/redo. Also, Undo

and Redo do not work inside of math mode. However, if you enter Math mode, change an equation, then leave math mode, Undo will revert to the old version of the equation, the one which existed before you entered Math mode.

1.4.4 Basic Mouse Bindings

We're not going to go into all of the mouse bindings here. Some of the other sections of this manual cover specific operations you can do with the mouse. Instead, we're going to cover the most basic mouse operations.

1. Motion

- Click the *left mouse button* once anywhere in the edit window. The cursor moves to the text under the mouse.
- The “Scroll Bar”

At the moment, LyX uses the XForms toolkit, which doesn't have scrollbars. So, the LyX Team improvised; we turned a slider into a scrollbar. As a result, the scrollbar won't work as it does in most other X-Windows programs:

- Click *any mouse button* on the scrollbar. The scrollbar slider moves to the spot under the mouse and LyX repositions the edit window appropriately.
- Move the mouse over the scrollbar slider and hold down any mouse button. You can now drag the slider and reposition the edit window.
- The Scrollbar Arrow Buttons:
Use the *left mouse button* to scroll by one line in the direction of the arrow.
Use the *right mouse button* to scroll a page in the *same* direction as the arrow.
Use the *middle mouse button* to scroll a page in the *opposite* direction of the arrow.

2. Selecting Text

- Hold down the *left mouse button* and drag the mouse. LyX selects the text between the old and new mouse positions. This is similar to how other programs work.
- Click the *middle mouse button* to paste text. LyX repositions the cursor under the mouse and puts the pasted material into the text at that position. Also, if you've selected any text, LyX copies it into the paste buffer and pastes it.

3. Footnotes, Margin Notes, Figure and Table Floats, etc.

Double click the *left mouse button* to open or close any of these. Also check the appropriate section of this manual for more details.

1.4.5 Basic Key Bindings

Again, we're not going to cover all of the keybindings. You should know how to use a keyboard by now. Besides, `Reference.lyx` contains a complete list of *all* of the keybindings.

Some keys, like `PageUp`, `PageDown`, `Left`, `Right`, `Up`, and `Down`, do exactly what you expect them to do. Other keys don't:

Tab There is no such thing as a tab stop in LyX. If you don't understand this, go read Section 3.2.1 and 3.3, especially sec. 3.3.6, right now. Yes, right now. If you're still confused, look in `Tutorial.lyx`.

Esc This is the "cancel key." It's used, generically, to cancel operations. Other parts of the manual will go into greater detail about this.

Home and **End** These move the cursor, respectively, to the beginning and end of a line.

Backspace and **Delete** *If* you have your keyboard set up correctly under X-Windows, `Backspace` works as expected and `Delete` deletes the character to the right of the cursor [if no text is selected].

If you haven't set up your keyboard under X-Windows, or have no idea what we mean by that, go read section 2.4 immediately. You'll save yourself a lot of headaches.

Then there are the modifier keys:

Control- This has a couple of different uses, depending on which keys it's used in combination with:

- With Backspace or Delete, it deletes an entire word instead of a single character.
- With Left and Right, it moves by words instead of characters.
- With Home and End, it moves to the beginning and the end of the document, respectively.

Shift- Use this with any of the motion keys to select the text between the old and new cursor positions.

Meta- As we noted earlier, this is the Alt- key on many keyboards. This key does many different things, but it also activated the *menu accelerator keys*. If you use this in combination with any of the underlined letters in a menu or menu item, it selects that menu item. If you use the accelerator key for a menu and then hit Space, you'll open that menu.

For example, the sequence “M-e p” pastes text. Typing “M-f Space” opens the File menu.

There are also other things bound to the Meta- key, but you'll have to check in `Reference.lyx` for more info.

1.5 Using LyX with Other Programs

1.5.1 Importing ASCII files

You can import text from an ASCII file using the Insert->Import ASCII File submenu. It contains two different options: As Lines and As Paragraphs.

Insert->Import ASCII File->As Lines puts each line of the file into its own LyX paragraph. This is useful if you're importing a text file with a simple list in it. However, if your text file contains paragraphs in it, LyX will mangle the paragraph if you use this form of import.

Insert->Import ASCII File->As Paragraphs preserves paragraphs in text files. Often in a text file, you didn't put the contents of an entire paragraph on one

line. You used **Return** to break up the paragraph into separate lines. Using the **As Paragraphs** option, LyX won't mangle such paragraphs. Anything between two consecutive blank lines goes into its own LyX paragraph. *But Remember:* you must make sure there is a *completely blank* line between each and every paragraph in your text file. If not, LyX might end up merging two paragraphs.

Use these options wisely. You have been warned!

1.5.2 Cut and Paste Between LyX and Other X Programs

The **Cut**, **Copy**, and **Paste** operations work only *inside* LyX. At the moment, you can't copy text from LyX to another X-Windows program. Sorry, but this is another one of those XForms-related problems.

The LyX team has managed, however, to get the other direction working. That is, you can copy text from another X-Windows program *into* LyX. This special form of pasting works like the ASCII import feature; you can paste as lines or as paragraphs. Use:

- Paste Primary Selection As Lines
- Paste Primary Selection As Paragraphs

from the Edit menu to do this.

1.5.3 Future Work

There are a few notes to go here.

First, version 0.12.x will contain an ASCII export option. It will convert a Dvi file to an ASCII text file, so the "export" actually requires a L^AT_EX run or two.

Also, the LyX Team plans to switch to the Qt toolkit after version 0.12.x, so several of the XForms-related problems will vanish.

Chapter 2

LyX Setup and Supporting Applications

2.1 Introduction

If you're using LyX on a system someone else has set up for you, then you can safely skip this chapter. It describes all of the things you need beyond the LyX binary and files distributed with it.

If you're installing LyX on your system, *you should read the README's that came with the LyX distribution*. Do that first. This chapter does not describe installation or setup of the LyX binary [Well, not everything ...]. It does describe all of the things you'll need to use LyX to its fullest.¹

2.2 Requirements

The version of LyX distributed as Linux binaries only needs X-Windows (X11R6). But it will compile under X11R5 as well. LyX is quite small (about 600K without XForms²) and doesn't even need much memory to store the documents. It's also not that fast,³ but fast enough to allow working on a

¹This is basically where we decided to document a bunch of info about running LyX, including what other programs you'll need to make LyX useful.

²Note from JOHN WEISS: Not entirely true! If XForms only has a static library available for your system, LyX will probably be closer to 1Mb in size. Matters are worse if LyX was compiled using debugging - it will be closer to 4Mb in size!

³It might take while if text in a new font has to be displayed, since the font has to be loaded into the X-server. LyX will not load fonts until they are really needed, so not all

386DX40 with 8MB RAM.⁴

If you want to print and preview, you also need a complete L^AT_EX2_& installation, including dvips and xdvi. L_YX will definitely not work with L^AT_EX2.09 (the changes you would have to do in the L_YX-sources are as much work as upgrading your L^AT_EX).

If you want to compile your own binary you also need the XForms-library. As of version 0.10 you will need to use version 0.81 of the XForms library. You can obtain it from:

- <http://braggs.phys.uwm.edu/xforms>
- <ftp://bloch.phys.uwm.edu/pub/xforms>
- <ftp://ftp.cs.ruu.nl/pub/XFORMS>

You also need the pixmap library (libXpm). Since this is usually a part of most Linux distributions it shouldn't be a problem. Just make sure you have the right pixmap library for your version of the XForms-library. There are some incompatibility issues. As of version 0.10 you will need version 4.7 or 4.8 of libXpm.

To compile L_YX... well, you wouldn't be reading this document if you hadn't already done so, would you?⁵

2.3 Basic L_YX Setup

Again, you probably wouldn't be reading this file if you didn't already have a working L_YX binary, so we won't discuss that here. There are a few things we do want to mention about L_YX setup and installation.

There are two ways to run L_YX. The first way is to install L_YX and all of its support files on your system. Of course, you need root privileges to do that. The second way to run L_YX doesn't require root access, letting you "install" L_YX somewhere in your own account. It's simple: just set the environment variable "LYX_DIR" to point to the L_YX directory.

fonts are immediately accessible in all possible styles and sizes.

⁴Note from MATTHIAS: "I know people who do this."

⁵If, by some odd chance, someone has handed you a printed version of this manual and the source files, please feel free to go ask *them* for help. Or, look at the README files that came in the source code distribution.

Here's an example. Suppose you've downloaded a binary distribution of LyX, version 0.10.0, and untarred it in your home directory. You'd then put the following in your `.cshrc` or your `.profile` file:

```
setenv LYX_DIR ${HOME}/lyx-0.10.0
```

or

```
export LYX_DIR=${HOME}/lyx-0.10.0
```

Once you've set this variable, you can then execute the LyX binary.

There are, additionally, many user-configurable options that you can feed to LyX. Upon startup, LyX attempts to read a file called `.lyxrc` in your home directory. If `${HOME}/.lyxrc` doesn't exist, LyX will read a global options file called `system.lyxrc`. The document `Configuration.lyx` contains more information about these setup files.

2.4 Setting Up the X-Windows Keyboard

To use LyX properly, you *must* set X up correctly. This is especially vital if you're using the international support features of LyX and want to use non-English keyboard mappings. Unfortunately, almost nobody bothers to do this, especially those who've installed Linux on a PC. Administrators of large systems can be guilty of this, too, so don't assume that you're safe if you're using a large system. Any user can instruct X how to use his or her keyboard. You needn't rely on your sysadmin for this - in fact, you *shouldn't!* The following two programs are all you need to set up your keyboard the way you want it.

2.4.1 xmodmap and xkeycaps

First of all read the man pages for these two programs. They are your best friends when you are trying to set up X key mapping correctly. If you don't have them, install them.

2.4.1.1 xmodmap

This document contains no information on how to use `xmodmap`. There is a sample `.Xmodmap` file in `Customization.lyx`. To load the new X keyboard mappings, place the command `xmodmap .Xmodmap` somewhere in your startup scripts [for example, `.cshrc`, `.profile`, `.login`, or `.xinitrc` are all possibilities].

2.4.1.2 xkeycaps

This program is a dream come true! It brings up a graphical version of your keyboard, allows you to make modifications, and then spits those modifications out to the standard output in a form readable by `xmodmap`. It is very useful when you're trying to design a new `.Xmodmap` file, though it will require you to do a bit of cut-and-pasting.

2.4.2 Modifiers and Mode_switch

LyX supports four modifiers: Shift [S-], Control [C-], Meta [M-], and “W-”⁶

2.4.3 Helpful Hints and Tips

First, open up two xterminals. Use one to edit a new `.Xmodmap` file and run `xkeycaps` from the other. Using `xkeycaps`, remap your keyboard the way you want it. There's a button in `xkeycaps` to output the new keymap. Once you hit it, `xkeycaps` will spit a bunch of stuff on the xterm you executed it from. Just copy and paste all of that into your `.Xmodmap` file, and you're done.⁷

Also, there are some things you can do to help you get oriented. Try executing the command `xmodmap -v -pm`. This will show you all of the currently active modifiers. Also try `xmodmap -v -pke | more` to see which keycode numbers are mapped to which symbolic names. It will also give you some idea of the syntax of the `.Xmodmap` file.

⁶Note from LARS GULLIK BJØNNES: “I use this one for AltGr on my keyboard.”
Editor’s Note: What is this thing? I’ve never seen it used before... -jw

⁷You could also save yourself some typing by executing `xkeycaps > .Xmodmap`. This will create a usable map file. Of course, if you hit the “output keymap” button in `xkeycaps` more than once, the resulting map file will be a mess. As with all things, `xkeycaps` is a tool, and only as intelligent as the person on the other end.

There's one thing you'll need to check. Make sure that your Delete and BackSpace keys are *not* defined as the same key symbol by X! Note that giving these two keys unique symbol names will not necessarily alter the behavior of your programs. Some programs bind Delete and BackSpace to the same operation. Emacs is one. Other programs, however, use Delete and BackSpace for different operations. LyX is one of these programs, and if you have Delete and BackSpace labeled with the same key symbol name, you'll have trouble using LyX.

2.5 LATEX

If you want to do more with LyX than simply create documents and spit out .tex files, you'll need LATEX.

In case you were wondering, LATEX is an extension to TeX, a document preparation system invented in 1984 by Donald Knuth.⁸ TeX takes a set of commands in an ASCII file and converts it to a “device-independent” format, or Dvi, for short. The Dvi file can then be sent to printers. TeX is programmable, and LATEX is nothing but a [really huge] set of TeX macros. LATEX will typically come as part of a TeX distribution, so all you need is a TeX package.

There are two version of LATEX commonly in use today. One is the older LATEX 2.09; the other is the newer LATEX 2 ϵ . LyX will only work with LATEX 2 ϵ and will gag on the older version 2.09.

Let us make that perfectly clear:

LyX WILL ONLY WORK WITH LATEX 2 ϵ !!!!!!

If your system has version 2.09, get the sysadmin to upgrade.

If you're using Linux, LATEX 2 ϵ should have come with your distribution. Look in the instructions that came with your Linux distribution [most likely a CD-ROM] and install the TeX package, if you didn't do so already. Everything you need will be there, along with some things you probably don't need.

For other systems, you'll probably have to talk to your sysadmin to get TeX/LATEX installed on your machine if it's not on there already.

⁸A note about pronunciation: TeX originated from the Greek letters, $\tau\epsilon\chi$, which rhymes with “blech.” That's how you pronounce “TeX” and “LATEX.” [If you're American, just pronounce the “X” as an “h” and you've got it.]

Oh, did we mention that LYX only works with LATEX 2 ε ?

2.6 Dvips and Ghostscript

2.6.1 What You Need

There's one more step you need to take if you want to print your LYX documents. Obviously, you'll need to make sure your printer is configured [see next section]. You'll also need to install these programs, if you don't have them already:

- dvips
- ghostscript
- xdvi
- ghostview

The latter two programs are previewer for files in Dvi and PostScript®⁹ format. If you don't know what a dvi-file is, you've probably also never worked with LATEX and should read the `Tutorial.lyx` file before proceeding further. `dvips` converts dvi-files into PostScript®, which is the format most printers use nowadays. For those of you using dot-matrix and inkjet printers, you'll want to filter the PostScript® through `ghostscript`, which is capable of creating output for a variety of printers. The following section on printer setup describes how to do this automatically everytime you print. For now, we'll concentrate on `dvips`.

2.6.2 Dvips

Whether you'll be running LYX on a large system or a Linux box at home, you should configure `dvips`. `dvips` will either “print” into a file, or send output directly to the printer, depending on how it's configured. If it is set up to print to a file, and if no filename is specified, it will simply turn `foo.dvi` into `foo.ps`. Some systems may have `dvips` set up to *always* send output to the printer. For LYX, you'll want the flexibility to do both.

⁹PostScript® is a registered trademark of Adobe Systems Incorporated, and is the main page description language in the UN*X world.

In order to inform `dvips` how to automagically convert a `.dvi` file into a `.foo` file, you need to have a config-file, “`config.foo`,” lying around somewhere. Typically, the `config.*` files for `dvips` will be in `/usr/lib/texmf/dvips` in most `TEX` distributions. Your system will probably be different, of course, so just look under the main `TEX` directory for a subdirectory called “`dvips`.” It’ll be there somewhere.

Typically, there will be at least one config-file: `config.ps`. Of course, some `TEX` distributions have to be different, and will come with a `config.lp` instead. Copy that file to `config.ps`, if one doesn’t exist already.

There’s one last thing you need to do to the config-file. There may exist a line that looks like, “`o | lpr`” [without the quotes, of course...]. Comment it out [put a “%” at the beginning of the line]. Otherwise, `dvips` will always send its output to the printer.

Once you’ve done all that, you can print to either a PostScript® printer or file from LyX. To print to a printer, you can always print to a file using “`|lpr -Pprintername`” as the output filename. Of course, you’ll probably want to use the “print to printer” option that LyX provides. If you’ve made sure a `config.ps` file exists, like we described above, and your default printer is called “`ps`”, you’re all set. LyX will use `dvips` with the option `-Pps` to print directly.

One last thing: some folks have to be different, and won’t have a printer named “`ps`”. Of course, you may have multiple printers, one called “`ps`”, another called “`ljfour`”, and so on. Guess what? You can make a config-file for them, too! If you create “`config.ljfour`” then `dvips` will recognize the option `-Pljfour`. You can use as many config-files as you like, one for each of your printers. The default printer for LyX can be specified in `.lyxrc`. You can also choose the desired printer from inside LyX, as described in a later section.

2.6.3 Ghostscript

If you thought all this nonsense about config-files for `dvips` was a pain, you’ll like `ghostscript`. No need to do any extra twiddling here; `ghostscript` runs just fine out of the box.

Now the bad news: if your printer doesn’t understand PostScript®, you’ll need to use `ghostscript` as a filter for your print spooler. That’s covered in numerous HOWTO’s and manuals. We also have a section that covers a little bit of this.

Some people don't seem to like using the `dvips` plus `ghostscript` combination. As alternative, you can use a program that converts the `dvi`-file directly into your printer language. You can specify this program in `.lyxrc`, too. There is a major disadvantage to this method. You can't include any PostScript® files, such as graphics, in your documents, since the printer-specific conversion programs don't understand PostScript®. For that reason, the LyX team highly recommends using `dvips` and `ghostscript` for printing.

2.6.4 Xdvi and Ghostview

These two programs are viewers. `xdvi` handles `.dvi` files, and `ghostview` interfaces with `ghostscript` to allow you to view PostScript® files.

A quick note on both of these programs. Both automatically update themselves if the viewed file¹⁰ changes. You can also force an update. So, once you've opened one of these two viewers, there's no reason to close it. Also, both programs are functionally the same, providing all of the same features.

The LyX team recommends using `xdvi` for fine tuning documents. Why? It's faster; there's one less layer of processing you need to do before you can view the changes. Here's an example:

1. Use `xdvi` to preview a document from LyX, and leave it running.
2. Make changes to the document using LyX.
3. To view those changes, just rerun LATEX on the LyX file. When LATEX's all done, click on the `xdvi` window, and voilà! `xdvi` will update itself.

Now, this doesn't mean `ghostscript` is useless. `ghostscript` is better suited to those occasions where you *must* view the PostScript® version of the document. For repeated changes that aren't PostScript® dependent, you're better off previewing with `xdvi`.

2.7 The Printer

Anyone working on a large system shouldn't have any problems here. Your sysadmin [or you, if you are the sysadmin] should already have the printers

¹⁰That means the `.dvi` or `.ps` file, not the files used to make these.

set up for your system. All you need to do is find out the name of the printer you want to use, and configure your `.lyxrc` as described in the last section.

Those of you using Linux, however, will have a bit more work to do. Many people now receive a Linux distribution, such as Red Hat or Slackware, on CD-ROM. They follow the install instructions, get Linux up and running, but never realize that they need to set up their printer. If you've never touched the file `/etc/printcap`, you need to set up your printer. We've written a little something to help you out with that; check out the "*A Printer Tutorial*" chapter in the "*Customizing LyX*" manual for help.

Chapter 3

LyX Basics

3.1 Document Types

3.1.1 Introduction

Before you do anything else, before you ever start writing a document, you need to decide what *type* of document you want to edit. Different types of documents use different types of spacing, headings, numbering schemes, and so on. Additionally, different documents use different paragraph environments, and format the title of your document differently.

A *document class* describes a group of properties common to a particular set of documents. By setting the document class, you automagically select these properties, making it easier to create the type of document you want. If you don't choose a document class, LyX picks one for you by default. So, it behooves you to change the class of your document.

Read on for info about the document classes you can choose from LyX, and how to fine-tune some of their properties.

3.1.2 The Various Document Classes

3.1.2.1 Overview

There are five standard document classes in LyX. They are:

Article for basic articles

Report for basic reports

Book for writing a book

Letter for US-style letters

Linuxdoc Used with the LinuxDoc package. It allows LyX to produce SGML output. SGML is a markup language and is the predecessor to HTML. The LinuxDoc package allows you to convert SGML to HTML or to the format used by `man` pages.

There are also four nonstandard classes, which LyX only uses if you have a L^AT_EX setup that supports them:

Amsart Journal articles in the style and format used by the AMS [American Mathematical Society]

Dinbrief für Briefe nach deutscher Art

Iletter per lettere all' italiana

Paper for use with the paper L^AT_EX document class [not in all L^AT_EX distributions]

There's also support for overhead projector slides and possibly other document classes coming up, so stay tuned!

We won't go into any detail about how to use these different document classes. That belongs in a separate chapter. Nor will we detail which document classes use what special paragraph environments. That, too, would fill its own chapter.¹ Instead, we'll list some of the common properties of all of the document classes.

3.1.2.2 Selecting a Class

You can select a class using the Document Layout popup. To open the Document Layout popup, select Document... from the Layout menu. Then use Class to select the class you want to use.

After you select a class, LyX then asks if you want to use the defaults for Pagestyle, Sides, Columns, Separation, and Extra Options. It's safe to hit Yes here. If you look at the Document Layout popup again, you'll notice options for all of these. So, you can always fine-tune the defaults for a given section.

¹Editor's Note: And, it will, too. I have plans to put such a chapter in `Reference.lyx`. Stay tuned.... -jw

3.1.2.3 Properties

In case you’re wondering what those “defaults” are for each of the document classes, here’s a quick table describing them:

	Pagestyle	Sides	Columns	Max. sectioning level
article	Plain	One	One	Section
report	Plain	One	One	Chapter
book	Headings	Two	One	Chapter
letter	Plain	One	One	none
linuxdoc	Plain	One	One	Section
amsart	Headings	One	One	Section
dinbrief	Plain	One	One	none
iletter	Plain	One	One	none
paper	Plain	One	One	Section

There is no default value of `Extra Options` or `Separation` for any of these classes. In fact, the `system.lyxrc` file [or your `~/.lyxrc` file] sets the default value of `Separation`.

You’re probably also wondering what “Max. sectioning level” means. There are several paragraph environments used to create section headings. Different document classes allow different types of section headings. Only two use the `Chapter` heading; the rest do not and begin instead with the `Section` heading. Some document classes, such as the three for letters, don’t use any section headings. In addition to `Chapter` and `Section` headings, there are also `Subsection`, `Subsubsection` headings, and so on. We’ll describe these headings fully in section 3.3.4.

3.1.3 Fine-Tuning the Defaults

Okay, we know we never told you what most of these “default options” set by the `Class` button do. That’s what this section is for.

Pagestyle This is another list, containing three options. It controls what sorts of headings and page numbers go on a page.²

²LATEX does this part.

	Empty	No page numbers or headings.
	Plain	Page numbers only.
	Headings	Page numbers and either the current chapter or section title and number. Whether LyX uses the current chapter or the current section depends on which is the maximum sectioning level.
Sides		No, LyX can't make your printer print on both sides of a sheet of paper! However, it can use a different format for odd-numbered pages than even-numbered pages. This way, if you <i>do</i> have a printer that duplexes, ³ your page number will always be in the upper right corner of the page and the left margin will have extra room for a binding. There are two toggle buttons here: One for single-sided documents, Two for double-sided documents.
Columns		Yes, this does control how many columns each page has. You can choose, using the toggle buttons, One or Two for the number of columns. Note that LyX won't show two columns on screen. That's impractical, often unreadable, and not part of the WYSIWYM concept. However, there <i>will</i> be two columns in the generated output.
Extra Options		The L ^A T _E X command <code>\documentclass</code> takes several options. LyX sets some of these automatically for you. This text box allows you to enter in others. Just type in a comma-separated list of options. See a good L ^A T _E X book to find out what kinds of additional options you can use.
Separation		This has its own section. See sec. 3.2.1 for a description of what this does.

³i.e. prints on both sides of a sheet of paper

3.1.4 Paper Size, Orientation, and Margins

There are several other options to set in the Document Layout popup. All of them are global options, but they have special purposes and only affect certain features. We describe what these options do in the same section that describes the features they affect.

There are two options that affect the overall layout of the document, so we'll describe them here:

Orientation Two toggle buttons choose whether to print the output as Landscape or as Portrait.

Papersize What size paper to print on. The choices are

- A4 with four different types of margin
- A5
- B5
- US Letter
- legal
- executive

It would also be nice to set the margins. At the time of this writing, you can only set the margins by adding the appropriate commands to the L^AT_EX preamble (see section 5.4.1). The LyX Team hopes to add a better interface in the future.

3.1.5 Important Note:

If you change a document's class, LyX has to convert *everything* into the new class. That includes the paragraph environments. Some paragraph environments are standard; all of the document classes have them. Some classes have special paragraph environments, however. If this is the case, and you change document classes, LyX sets the missing paragraph environments to Standard and places an error box at the beginning of the paragraph. Just click on them and you'll get a message popup that tells you about the conversion and why it failed.

3.2 Paragraph Indentation and Separation

3.2.1 Introduction

Before describing all of the various paragraph environments, we'd like to say a word or two about paragraph indentation.

Everyone seems to have their own convention for separating paragraphs. Most Americans indent the first line of a paragraph. Others don't indent but put extra space between the paragraphs. LyX uses the same convention you find among typographers. The *first* paragraph of a section, or after a figure, an equation, a table, a list, etc., is *not* indented. Only a paragraph following another paragraph gets indented. Some people don't like this convention, but if you want to use indented paragraphs, you'll have to live with.⁴

The space between paragraphs, like the line spacing, the space between headings and text — in fact, all of the spacings for just about everything are pre-coded into LyX. As we said, you don't worry about how much space to add between what. LyX takes care of that. In fact, these pre-coded vertical spacings aren't a single number but a range. That way, LyX can squish or stretch the space between lines to make sure figures fit on a page with text, so that sections don't start at the bottom of a page, and so on.⁵ However, pre-coded doesn't mean you can't change them. LyX gives you the ability to globally change *all* of these pre-coded spacings by some factor. We'll explain more later.

3.2.2 Global Indentation Method

To select the default method of separating paragraphs, select **Document...** from the **Layout** menu. This opens the **Document Layout** popup. Select **Indent** or **Skip** to indent paragraphs or add extra space between paragraphs, respectively.

⁴There is a way to force L^AT_EX to indent all paragraphs. LyX won't show this, of course, but L^AT_EX *will* print it that way. You'll need to get a special package and insert an appropriate command in the preamble. [*Editor's Note: I'll insert this info when I get the time. - jw*]

⁵Actually, L^AT_EX does this when LyX goes to produce a printable file.

3.2.3 Fine-Tuning

You can also change the separation method of a single paragraph. Choose **Paragraph...** from the **Layout** menu to open the **Paragraph Layout** popup. Toggle the **No Indent** button to change the state of the current paragraph. If paragraphs indent by default, this button will be inactive at first. If paragraphs have no indentation but use extra space for separation, this button will be depressed initially.

You should only need to change the indentation method for a single paragraph if you need to do some fine-tuning. Typically, you'll select **Indent** or **Skip** for the entire document and edit away.

3.2.4 Changing Line Spacing

Fooled you! This section is really about baseline stretching.

Actually, the title of this section is just an eye-catcher. If you want to change the line spacing, you should read this section and 3.2.1. If you're used to using your computer like a typewriter and manually setting the spacing between each and every line, you might want to read the tutorial, too.

Because LyX is a high-level word processor, the space between every single line depends on its context. A list has different spacing between its items, between lines in an item, and between itself and other paragraphs. Section headings use different spacings altogether. So too with the space between lines in a normal paragraph. Changing all of these default spacings takes tons of work and expert knowledge of L^AT_EX programming. That's why document classes exist.

Then again, *why* would you want to change all of those default spacings *unless* you were creating a new document class?

The *baseline stretch* is a proportionality constant that changes the default spacing of *all* lines at once.⁶ To change the global *baseline stretch*, select **Document...** from the **Layout** menu to open the **Document Layout** popup. Then change the **Baselinestretch** slider to select how much to stretch the *baseline*. Here's a quick table to get you oriented:

⁶Actually, the *baseline stretch* “changes” the height of the tallest letter by some factor. The height of the characters is what LyX uses to determine all vertical spacings. By telling LyX that the letters are taller or shorter than they really are, you can alter all of those vertical spacings proportionally.

Baselinestretch value	Equivalent typewriter line spacing
.75	single-spaced
1.0 [default]	1.5 spacing
1.5	double-spaced
2.0	triple-spaced

You can select these values or any value in-between. Note, however, that LyX may still compress or stretch this spacing to make sure it fits everything on each page.

There are ways to add some vertical space manually for fine-tuning. We'll talk more about this later. You should *never* need to change the line-spacing in a single paragraph. LyX does this for you through paragraph environments.

3.3 Paragraph Environments

3.3.1 Overview

The paragraph environments correspond to the various `\begin{environment}...`
`\end{environment}` command sequences in an ordinary L^AT_EX file. If you don't know L^AT_EX, or the concept of a paragraph environment is totally alien to you, we urge you to look in the document `Tutorial.lyx`. `Tutorial.lyx` also contains many more examples than this section does.

A paragraph environment is, simply, a “container” for a paragraph which gives that paragraph certain properties. This can include a particular style of font, different margins, a numbering scheme, labels, and so on. Additionally, you can “nest” the different environments inside one another, allowing one environment to inherit some of the properties of another. The different paragraph environments totally replace the need for messy tab stops, on the fly margin adjustment, and other holdovers from the days of typewriters. There are several paragraph environments which are specific to a particular document type. We'll only be covering the most common ones here.

To choose a new paragraph environment, use the pull-down box on the left end of the toolbar. [Click on the arrow to open and close it.] LyX will change the environment of the *entire* paragraph in which the cursor sits. You can also change the environment of an entire group of paragraphs if you select

them before choosing the new environment.

Note that hitting **Return** will *typically* create a new paragraph using the **Standard** paragraph environment. We say “typically” because this isn’t always the case.⁷ Usually, starting a new paragraph resets both the paragraph environment and the nesting depth [more on nesting in section 3.4]. Sometimes, however, LyX keeps the old environment. At the moment, all this is context-specific; you’re better off expecting **Return** to reset the paragraph environment and depth. If you want a new paragraph to keep the current environment and depth, use **M-Return** instead.⁸

3.3.2 Standard

The default paragraph environment is **Standard**. It creates a plain paragraph. If LyX resets the paragraph environment, this is the one it chooses. In fact, the paragraph you’re reading right now [and most of the ones in this manual] are in the **Standard** environment.

You can nest a paragraph using the **Standard** environment in just about anything else, but you can’t really nest anything in a **Standard** environment.

3.3.3 Document Titles

This will change soon. Currently, there are two types of titles. LyX has its own way to create a title page. L^AT_EX has a series of commands and provides more power and flexibility. In the future, LyX will support the L^AT_EX title page commands more transparently than at present.

3.3.3.1 The LyX Title

The paragraph environment **Title** creates a title page generated by LyX. On screen, it centers text, places the text in the “very large” size, bold sans-serif character style. There are **VFills** above and below the text. [We’ll cover **VFills**

⁷If you are in one of these environments:

- | | | | |
|--|--|--|--|
| <ul style="list-style-type: none"> ● Quote ● Quotation | <ul style="list-style-type: none"> ● Verse ● Itemize | <ul style="list-style-type: none"> ● Enumerate ● Description | <ul style="list-style-type: none"> ● List |
|--|--|--|--|

LyX keeps the old paragraph environment when you hit **Return**, rather than resetting it to **Standard**. LyX will still reset the nesting depth, however.

⁸This invokes the function `break-paragraph-keep-layout`.

and how to use them in section 4.3.2.] LyX uses the appropriate commands to do the same in the L^AT_EX version of the file. Additionally, LyX also sets the page style to “empty,” so that no headings or page numbers appear on the title page.

The result is a blank page, containing text centered both horizontally and vertically. The text is Sans Serif, boldfaced, and in the second-to-largest font size.

Note that if you try to put a title page in the middle of the document, weird things may happen, and we won’t vouch for your sanity.

3.3.3.2 L^AT_EX Title Pages

A L^AT_EX title page has three parts: the title itself, the name[s] of the author[s] and a “footnote” for thanks or contact information. For certain types of documents, L^AT_EX places all of this on a separate page along with today’s date. For other types of documents, the title “page” goes at the top of the first page of the document. Of course, as with all spiffy things L^AT_EX, you need to “activate” the title page using the command `\maketitle`.

You may be asking yourself, “Why do I need to know any of this?” Simple. LyX provides an interface to the L^AT_EX title page commands through the paragraph environments L^AT_EX Title, Author, and Date. Here’s how you use them:

- Put the title of your document in the L^AT_EX Title environment.
- Put the author name in the Author environment.
- If you want the date to have a certain appearance, want to use a fixed date, or want other text to appear in place of today’s date, put that text in the Date environment. Note that using this environment is optional.
- Follow this with the `\maketitle` command. [You can use the L^AT_EX paragraph environment or mark the code as L^AT_EX. See section 5.3 for more details how to do this.]

Be sure to do this at the top of the document.

Please note that the LyX Team is working on a better interface to the L^AT_EX title page commands. All of these environments for producing title pages may change and/or disappear, to be replaced by something better in the future.

3.3.4 Headings

There are nine paragraph environments for producing section headings. LyX takes care of the numbering for you. All you need to do is decide what you're going to call section 3 of chapter 9.

3.3.4.1 Numbered Headings

There are 6 numbered types of section headings. They are:

1. Chapter
2. Section
3. Subsection
4. Subsubsection
5. Paragraph
6. Subparagraph

LyX labels each heading with a series of numbers, separated by periods. The numbers describe where in the document you are. These headings all subdivide your document into different pieces of text. For example, suppose you're writing a book. You group the book into chapters. LyX does similar grouping:

- Either **Chapter** or **Section** is the maximum sectioning level.
- **Chapters** are divided into **Sections**
- **Sections** are divided into **Subsections**
- **Subsections** are divided into **Subsubsections**
- **Subsubsections** are divided into **Paragraphs**
- **Paragraphs** are divided into **Subparagraphs**

Note: not all document types use the **Chapter** heading as the maximum sectioning level. In that case, the **Section** is the top-level heading.

So, if you use the **Subsubsection** environment to label a new sub-subsection, LyX labels it with its number, along with the number of the subsection, section, and, if applicable, chapter that it's in. For example: the fifth section of the second chapter of this book has the label "2.5".

3.3.4.2 Unnumbered Headings

There are 3 types of unnumbered section headings. They are:

1. **Section***
2. **Subsection***
3. **Subsubsection***

The “*” after each name means that these headings are not numbered. They work the same as their numbered counterparts.

3.3.4.3 Changing the Numbering

You can also alter which sectioning levels get numbered and which ones appear in the Table of Contents. Now, this doesn't remove any of the levels; that's preset in the document class. Certain classes start with **Chapter** and go down to the **Subparagraph** level. Others start at **Section**. Similarly, not all document classes number all sectioning levels. Most don't number **Paragraph** or **Subparagraph**. This is something you can change.

Open the **Document Layout** popup [via the **Document...** item in the **Layout** menu]. You should see a slider labelled **Sec. Num. Depth**. That slider controls how far down in the sectioning hierarchy LyX numbers a section heading. Unfortunately, the number you choose with the slider is really goofy, so here's a table of values and what they do:

Sec. Num. Depth value:	LyX numbers these section headings:
-1	no numbering
-0 and 0	Chapter
1	Chapter through Section
2	Chapter through Subsection
3	Chapter through Subsubsection
4	Chapter through Paragraph
5	Chapter through Subparagraph

Of course, if you’re using a document class that doesn’t use Chapter headings, then the numbering begins at the Section heading, and “0” also corresponds to “no numbering.”

There’s another slider on the Document Layout popup, called Toc. Depth. It works the same way as Sec. Num. Depth, only it controls which sectioning levels appear in the Table of Contents. This is a great control to have. Suppose you wanted to number *all* sectioning heading, but you only wanted Chapters, Sections, and Subsections in the Table of Contents. You’d just set Sec. Num. Depth to “5” and Toc. Depth to “2” and voilá! You’re all set.

3.3.4.4 Special Information

The following information applies to Chapter, Section, Subsection, Subsubsection, Paragraph, Subparagraph as well as Section*, Subsection*, and Subsubsection*:

- You cannot use a footnote or a margin note in any of these environments.
- You can use inlined math in these environments.
- You cannot do any nesting with these environments.
- You can use labels and cross-references to refer to their numbers.

As for examples of these paragraph environments - look around you! We’re using them everywhere in the manuals.

3.3.5 Quotes and Poetry

LyX has three paragraph environments for writing poetry and quotations. They are **Quote**, **Quotation**, and **Verse**. Forget the days of changing linespacing and twiddling with margins. These three paragraph environments already have those changes built-in. They all widen the left margin and add a bit of extra space above and below the text they contain. They also allow nesting, so you can put a **Verse** in a **Quotation**, as well as in some other paragraph environments.

There is another feature of these three paragraph environments: they do *not* reset to **Standard** when you break a paragraph. So, you can type in that poem and merrily hit **Return** without worrying about the paragraph environment changing on you. Of course, that means that, once you're done typing in that poem, you have to change back to the **Standard** environment yourself.

3.3.5.1 Quote and Quotation

Now that we've described the similarities of these three environments, it's time for the differences. **Quote** and **Quotation** are identical except for one difference: **Quote** uses extra spacing to separate paragraphs and never indents the first line. **Quotation** *always* indents the first line of a paragraph and uses the same line spacing throughout.

Here's an example of the **Quote** environment:

This is in the **Quote** environment. I can keep writing, extending this line out further and further until it wraps. See - no indentation!

Here's the second paragraph of this quote. Again, there's no indentation, but there is extra space between me and the other paragraph.

That ends that example. Here's another example, this time in the **Quotation** environment:

This is in the **Quotation** environment. If I keep writing, you'll see the indentation. If your country uses a writing style that

shows off new paragraphs by indenting the first line, then **Quotation** is the environment for you! Well, you'd use it *if* you were quoting other text.

Here's a new paragraph. I could ramble on and on, like a politician at election time. If I did that, though, you'd get bored.

That was our other example. As the example notes, **Quote** is for those people who use extra space to separate paragraphs. They should put quotes in the **Quote** environment. Those who use indentation to mark a new paragraph should use the **Quotation** paragraph environment for quoted text.

3.3.5.2 Verse

Verse is a paragraph environment for poetry, rhymes, verses, and so on. Here's an example:

This is in Verse
Which I did not rehearse!

It could be much worse. This line could be long, very long, oh so long, so very long that it wraps around. It looks okay on screen, but in the printed version, the extra lines are indented a bit more than the first. Okay, so it's turned to prose and doesn't rhyme anymore. So sue me.

To break a line
And make things look fine
Use C-Return.

As you can see, **Verse** does not indent both margins. Each stanza of the verse or poem is in its own paragraph. To separate the individual lines of a stanza, use the **break-line** function, C-Return.

3.3.6 Lists

This is an area where LyX clearly outshines standard word processors. One of the most common complaints and “bug” reports on the LyX Developer’s list is, “I can’t put in more than one space!” Typically, the user in question is looking for some way to indent text so he can make an outline or a list. After all, on the brand-name commercial word processors, if you want to write a

list, you need to apply tab stops, indents, an a plethora of other horizontal spacing commands.

But why should *you* have to do this at all? Tab stops are fine for a typewriter, where you have no other way to indent text. A computer, on the other hand, is quite good at counting and doing things repeatedly. So, you shouldn't need to keep track of list numbers, indentations, and such. And with LyX, you don't.

LyX has four different paragraph environments for creating different kinds of lists. In the **Itemize** and **Enumerate** environments, LyX labels your list items with bullets or numbers, respectively. In the **Description** and **List** environments, LyX lets you provide your own label. We'll present the individual details of each type of list next after describing some general features of all four of them.

3.3.6.1 General Features

The four paragraph environments for lists differ from the other environments in several ways. First, LyX treats each paragraph as a list item. Hitting Return does *not* reset the environment to Standard but keeps the current environment and creates a new list item. The nesting depth is typically reset, however. If you want to keep both the current nesting depth and paragraph environment, you should use M-Return to break paragraphs.

You can nest lists of any type inside one another. In fact, LyX changes the labels on some list items depending on how its nested. If you intend to use any of the list paragraph environments, we *strongly urge* you to read all of section 3.4.

3.3.6.2 Itemize

The first type of list we'll describe in detail is the **Itemize** paragraph environment. It has the following properties:

- Each item has a particular bullet or symbol as its label.
 - LyX uses the same symbol for all of the items in a given nesting level.
 - The symbol appears at the beginning of the first line.

- The items can be any length. LyX automatically offsets the left margin of each item. The offset is always relative to whatever environment the `Itemize` list may be in.
- If you nest an `Itemize` environment inside another `Itemize` environment, the label changes to a new symbol.
 - There are four different symbols for up to a fourfold nesting.
 - LyX always shows the same symbol, an asterisk, on screen.
 - See section 3.4 for a full explanation of nesting.

Of course, that explanation was also an example of an `Itemize` list. The `Itemize` environment is best suited for lists where the order doesn't matter.

We said that different levels use different symbols as their label. Here's an example of all four possible symbols. Note that those of you reading this manual online won't see any difference.

- The label for the first level `Itemize` is a large black dot, or bullet.
 - The label for the second level is a dash.
 - * The label for the third is an asterisk.
 - The label for the fourth is a centered dot.
 - * Back out to the third level.
 - Back to the second level.
- Back to the outermost level.

These are the default labels for an `Itemize` list. You can customize these labels by adding the correct commands to the L^AT_EX preamble (see section 5.4.1). Of course, LyX won't know about them; that's the whole point to the WYSIWYM concept. Any customizations you make appear in the printed document.

Notice how the space between items decreases with increasing depth. We'll explain nesting and all the tricks you can do with different depths in section 3.4. Be sure to read it!

3.3.6.3 Enumerate

The `Enumerate` environment is the tool to use to create numbered lists and outlines. It has these properties:

1. Each item has a numeral as its label.
 - (a) The type of numeral depends on the nesting depth.
2. LyX automatically counts the items for you and updates the label as appropriate.
3. Each new `Enumerate` environment resets the counter to 1.
4. Like the `Itemize` environment, the `Enumerate` environment:
 - (a) Offsets the items relative to the left margin. Items can be any length.
 - (b) Reduces the space between items as the nesting depth increases.
 - (c) Uses different types of labels depending on the nesting depth.
 - (d) Allows up to a fourfold nesting.

Unlike the `Itemize` environment, `Enumerate` *does* show the different labels for each item. Here is how LyX labels the four different levels in an `Enumerate`:

1. The first level of an `Enumerate` uses Arabic numerals followed by a period.
 - (a) The second level uses lower case letters surrounded by parentheses.
 - i. The third level uses lower-case Roman numerals followed by a period.
 - A. The fourth level uses capital letters followed by a period.
 - B. Again, notice the decrease in inter-item spacing as the nesting depth increases.
 - ii. Back to the third level
 - (b) Back to the second level.
2. Back to the outermost level.

Once again, you can customize the type of numbering used in the **Enumerate** environment. It involves adding commands to the L^AT_EX preamble (section 5.4.1), however. As stated earlier, such customization only shows up in the printed version, not on the LyX screen.

There is more to nesting **Enumerate** environments than we've stated here. You *really* should read section 3.4 to learn more about nesting.

3.3.6.4 Description

Unlike the previous two environments, the **Description** list has no fixed label. Instead, LyX uses the first "word" of the first line as the label. Here's an example:

Example: This is an example of the **Description** environment.

LyX typesets the label in boldface and puts extra space between it and the rest of the line.

Now, you're probably wondering what we mean by, "uses the first 'word'." As stated earlier,⁹ the Space key does not add a whitespace character, but separates words from one another. Inside of a **Description** environment, the Space key tells LyX to end the label if we're at the beginning of the first line of an item. [*Editor's Note: Hopefully, someone will change this. It would be nice if, say, the Tab key terminated the label, since LATEX allows you to use a resizable space in the label of a description list. -jw*]

However, what if you want or need to use more than one word in the label of a **Description** environment? Simple: use a **Protected Blank**. [Use either C-Space or **Special Characters->Protected Blank** from the **Insert** menu. See sec. 4.3.1 for more info.] Here's an example:

Second Example: This one shows how to use a **Protected Blank** in the label of a **Description** list item.

Usage: You should use the **Description** environment for things like definitions and theorems. Use it when you need to make one word in particular stand out in the text that describes it. It's not a good idea to use a **Description** environment when you have an entire sentence that you want to describe. You're better off using **Itemize** or **Enumerate** and nesting several **Standard** paragraphs into them.

⁹*Editor's Note: This should be stated in the beginning somewhere... -jw*

Nesting: You can, of course, nest **Description** environments inside one another, nest them in other types of lists, and so on. Read section 3.4 to learn about nesting.

Notice that after the first line, LyX indents subsequent lines, offsetting them from the first line.

3.3.6.5 The LyX List

The **List** environment is a LyX extension to L^AT_EX.

Now, if you jumped here without reading sections 3.3.6.2-3.3.6.4, you've goofed. The **List** environment does *not* create numbered lists. That's what **Enumerate** does, and it's documented in section 3.3.6.3.

Like the **Description** environment the **List** environment has user-defined labels for each list item. There are some key differences between this list environment and the other three:

- | | |
|---------------|--|
| item labels | LyX uses the first “word” of each line as the item label. The first Space after the beginning of the first line of an item marks the end of the label. If you need to use more than one word in an item label, use a Protected Blank [C-Space] between them. |
| margins | As you can see, LyX uses different margins for the item label and the body of the item text. The body of the text has a larger left margin, which is equal to the default label width plus a little extra space. |
| label width | LyX uses one of two things for the label width: the actual width of the label, or the default width, whichever is larger. If the actual width is larger, then the label “extends” into the first line. In other words, the text of the first line isn't aligned with the left margin of the rest of the item text. |
| default width | You can very easily set this default width. It's quite painless, actually. So, you can easily ensure that the text of all items in a List environment have the same left margin. |
| uses | You should use the List environment the same way you'd use as Description list: when you need one word to stand out from the text that describes it. The List environment gives you another way to do this, using a different overall layout. |

nesting You can nest **List** environments inside one another, nest them in other types of lists, and so on. They work just like the other list paragraph environments. Read section 3.4 to learn about nesting.

As you can see, this is a feature-packed paragraph environment!

To change the default width of the label, select the items in the list to change. You can also simply move the cursor into a **List** item if you want to change only its label width. Now open the Paragraph Layout popup [use **Paragraph...** in the **Layout** menu] and find the **Label Width** text box. The text in the **Label Width** box determines the default label width. If you really, really want to, you can use the text of your largest label here, but you don't need to. We recommend using the letter "M" multiple times. It's the widest character and is a standard unit of width in L^AT_EX.¹⁰ The default label width in the example **List** is 6 "M"s wide. Using "M" as your unit of width in the **Label Width** box has one more advantage: you don't need to keep changing the contents of **Label Width** everytime you alter a label in a **List** environment.

There's yet another feature of the **List** environment we need to tell you about. As you can see in the examples, LyX left-justifies the item labels by default. In reality, there is an **HFill** built into the end of the label. We'll document **Hfills** later in section 4.3.1. You can use additional **Hfills** to change how LyX justifies the item label. Here are some examples:

Left The default for **List** item labels.

Center One **HFill** at the beginning of the label centers it.

Right #1 You can sort-of right justify the label by using several **Protected Blanks** at the beginning of the line. As you can see, however, it alters the margin of the first line. It'll be a pain in the butt to figure out just how many **Protected Blanks** are enough.

Right #2 This is somewhat better, though still a kludge. Uses several **Hfills** at the beginning of the label. [*Editor's Note: This is*

¹⁰Of course, you could use some other character multiple times, too. Or, you could get fancy and use combinations of "l"s, "o"s and "M"s. However, the width of the letter "M" is a standard unit of horizontal space under L^AT_EX. That's why we recommend using "M" multiple times.

*another one of those things that seemed okay at the time,
but now look really klunky. The developers should change
it. - jw]*

Don't worry if you have no idea what **Hfills** are yet. Just remember that you can use them to customize the look of the **List** environment.

That does it for the four paragraph environments for making lists. Oh - did we mention that you should read about nesting environments in section 3.4 if you want to use any of these list environments?

3.3.7 Letters

3.3.7.1 Address and Right Address: An Overview

Although LyX has document classes for letters, we've also created two paragraph environments called **Address** and **Right Address**.¹¹ To use the letter class, you need to use specific paragraph environments in a specific order, otherwise L^AT_EX gags on the document. In contrast, you can use the **Address** and **Right Address** paragraph environments anywhere with no problem. You can even nest them inside other environments, though you can't nest anything in them.

Of course, you're not limited to using **Address** and **Right Address** for letters only. **Right Address**, in particular, is useful for creating article titles like those used in European academic papers.

3.3.7.2 Usage

The **Address** environment formats text in the style of an address, which is also used for the opening and signature in some countries. Similarly, the **Right Address** environment formats text in the style of a right-justified address, which is used for the sender's address and today's date in some countries. Here's an example of each:

¹¹Note from MATTHIAS: I'm a bit proud about this right address layout. Try to reach the same typesetting effect with usual word processors. You will have to create a frame and position it manually with the mouse and all those funny things.

Right Address
 WhoAmI
 WhereAmI
 When is it? What is today?

That was **Right Address**. Notice that the lines all have the same left margin, which LyX sets to fit the largest block of text on a single line. Here's an example of the **Address** environment:

WhoAreYou
 Where do I send this
 Your post office and country

As you can see, both **Address** and **Right Address** add extra space between themselves and the next paragraph. Speaking of which, if you hit **Return** in either of these environments, LyX resets the nesting depth and sets the environment to **Standard**. This makes sense, however, since **Return** is the **break-paragraph** function, and the individual lines of an address are not paragraphs. Thus, you'd use **break-line** [C-Return or Special Character->**Linebreak** from the **Insert** menu] to start a new line in an **Address** or **Right Address** environment.

3.3.8 Academic Writing

Most academic writing begins with an abstract and ends with a bibliography or list of references. LyX contains paragraph environments for both of these.

3.3.8.1 Abstract

The **Abstract** environment is used for the abstract of an article. Technically, you *could* use this environment anywhere, but you really *should* only use it at the beginning of the document, after the title. Also, don't bother trying to nest **Abstract** in anything else or vice versa. It won't work.

The **Abstract** environment does several things for you. First, it puts the centered label "Abstract" above the text. The label and the text of the abstract are separated by some extra vertical space. Second, it typesets everything in a smaller font, just as you'd expect. Lastly, it adds a bit of extra vertical space between the abstract and the subsequent text. Well,

that's how it will appear on the LyX screen. If your document is in the "report" class, the abstract actually appears on a separate page in the printed version of the file.

Starting a new paragraph by hitting Return does *not* reset the paragraph environment. The new paragraph will still be in the **Abstract** environment. So, you will have to change the paragraph environment yourself when you finish entering the abstract of your document.

We'd love to give you an example of the **Abstract** environment, but we can't, since this document is in the "book" class. If you've never heard of an "abstract" before, you can safely ignore this environment.

One last note: the **Abstract** environment is only useful in the "article" and "report" document classes [as well as "amsart," which is just a specialized version of "article"]. The "book" document class ignores the **Abstract** completely, and it's utterly silly to use **Abstract** in the "letter" document class.

3.3.8.2 Bibliography

The **Bibliography** environment is used to list references. Technically, you *could* use this environment anywhere, but you really *should* only use it at the end of the document. Also, don't bother trying to nest **Bibliography** in anything else or vice versa. It won't work.

The **Bibliography** environment requires special handling. This environment is actually a kludge, and it may change or disappear entirely in future versions.

When you first open a **Bibliography** environment, LyX add a large vertical space, followed by the heading "Bibliography" or "References," depending on the document class. The heading is in a large boldface font. Each paragraph of the **Bibliography** environment is a bibliography entry. Thus, hitting Return does *not* reset the paragraph environment. Each new paragraph is still in the **Bibliography** environment.

At the *beginning* of the *first line* of each paragraph, you need to put in special text for an entry label. After you decide on a label, move to the beginning of the first line of the bibliography entry. Then turn on **T_EX** mode using **T_EX Style** from the **Layout** menu. [You can also use the keybinding M-c t or the toolbar button with the word "T_EX" in red.] Now type in a "{" character, followed by the label, followed by a "}" character. You can now turn off **T_EX** mode using M-c Space. Note that **T_EX** code appears in red.

For example, suppose your first entry in the bibliography was a book

about L^AT_EX. We could choose the label “`latexguide`” for that entry. So, at the beginning of the first line, you would put the text “`\{latexguide\}`” and mark it as T_EX code.

This label isn’t useless. You can refer to your bibliography entries using the L^AT_EX “`\cite{}`” command. Just put the label inside the “`\{ \}`” and don’t forget to mark the command as T_EX code. For example, to refer to our example entry, we’d use “`\cite{latexguide}`” marked as T_EX code. When LyX produces the final output, in place of the label and the “`\cite{}`” commands appear a number in square brackets.

An example of the **Bibliography** appears [where else] at the end of this document. “See [4] or [3]” is an example of how to cite two of the entries in it.

One last note — in order to use bibliographies and the “`\cite{}`” command, you need to run L^AT_EX *twice* on your document. Otherwise, the reference numbers will be incorrect.

3.3.9 Special Purpose

There are three standard paragraph environments that simply don’t fit any category, as they are very specialized for a particular purpose. We’ll point out the highlights and uses of each.

3.3.9.1 Caption

The **Caption** environment is the default paragraph environment for **Figure Floats** and **Table Floats**. On the LyX screen, you’ll see either the label “Figure:” or “Table:”, depending on which type of **Float** it’s in. Additionally, the **Caption** environment generates a figure or table number in the final output.

You can’t really nest things into a **Caption** environment or vice versa. Additionally, hitting **Return** resets the paragraph environment to **Standard**, so a **Caption** can only be a single paragraph.

You cannot use a **Caption** environment outside of a **Figure Float** or a **Table Float**. See sections 4.4 and 4.5 for more information on **Figure Floats** and **Table Floats**.

3.3.9.2 LyX-Code

The LyX-Code environment is another LyX-extension. It typesets text in a typewriter-style font. It also treats the Space key as a fixed whitespace;¹² this is the only case in which you can type multiple whitespaces in LyX. If you need to insert blank lines, you'll still need to use C-Return [the break-line function]. Return breaks paragraphs. Note, however, that Return does *not* reset the paragraph environment. So, when you finish using the LyX-Code environment, you'll need to change the paragraph environment yourself. Also, you *can* nest the LyX-Code environment inside of others.

There are a few quirks with this environment:

- You cannot use C-Return at the beginning of a new paragraph [i.e. you can't follow Return with a C-Return].
- You can't follow a C-Return with a Space.
 - Use a Return to begin a new paragraph, then you can use a Space.
 - Or: use C-Space instead.
- You can't have an empty paragraph or an empty line. You must put at least one Space in any line you want blank. Otherwise, L^AT_EX generates errors.
- You cannot get the typewriter double quotes by typing " since that will insert *real* quotes. You get the typewriter double quotes with C-'' or C-q.

Here's an example:

```
#include<stdio.h>

void main(void)

{
    printf("Hello World\n");
    exit(0);
}
```

¹²In the LyX-Code environment, the Space key is treated as a Protected Blank instead of an end-of-word marker.

This is just the standard “Hello world!” program.

LyX-Code has one purpose: to typeset code, such as program source, shell scripts, rc-files, and so on. Use it only in those very, very special cases where you need to generate text as if you used a typewriter.

3.3.9.3 L^AT_EX

The L^AT_EX paragraph environment has a specific purpose: to pass large blocks of commands to L^AT_EX. It has the following features:

- Text appears in red, indicating that it is L^AT_EX code.
- You can insert whitespace multiple times using the Space key [i.e. Space gets treated as a Protected Blank].
 - This does not work, however, after a C-Return. Use C-Space in that case.
- If you wish to break up your L^AT_EX commands over several lines, use C-Return to break the lines.
- The Return key resets the paragraph environment to Standard.
- You *can* nest a L^AT_EX environment in other environments.

See section 5.3 for more information.

3.4 Nesting Environments

3.4.1 The Big Deal

Throughout the previous sections, we’ve been constantly nagging you to “go read section 3.4.” So, you’re probably wondering what the big deal is.

The big deal is that LyX differs rather strongly from the traditional “wordprocessor-as-overglorified-typewriter” concept. With a typewriter, text is merely ink on a page. Most wordprocessors aren’t much better, treating text as pixels on the screen and bytes in memory. In contrast, LyX treats text as a unified block with a particular context and specific properties. However, what if you wanted one “block” to inherit some of the properties of another “block?”

Here's a more specific example: outlines. You have three main points in your outline, but point #2 also has two subpoints. In other words, you have a list *inside* of another list, with the inner list “attatched” to item #2:

1. one
2. two
 - (a) sublist - item #1
 - (b) sublist - item #2
3. three

How do you put a list inside of a list?

By now, the answer should be obvious: you nest one list inside the other. However, nesting isn't just limited to lists. In LyX, you can nest just about anything inside anything else, as you're about to find out. This is the real power of nesting paragraph environments.

3.4.2 What You Can and Can't Nest

Before we fire a list of paragraph environments at you, we need to tell you a little bit more about how nesting works.

The question of nesting is a bit more complicated than a simple yes or no, can you or can't you. There's also the question of how. Can you nest this environment into anything else? Can you nest another environment into it? A “yes” to one of these doesn't guarantee a “yes” to the other.

The paragraph environments in LyX can do one of three things when it comes to nesting. First, an environment may be completely unnestable. Second, there are environments that are fully nestable. You can nest them inside of things and you can also nest other things inside of them. There is one last type of environment. You can nest them into other environments, but that's it. You can't nest anything into them.

Here's a list of the three types of nesting behavior, and which paragraph environments have them:¹³

¹³For some odd reason, LyX allows you to fully nest both `Bibliography` and `Abstract`. Also, LyX allows you to nest `Title`, `LATEX Title`, `Author`, and `Date` into other environments. We urge you not to. LATEX may barf if you try it. Then again, it may not. We don't know for certain. However, it makes no sense contextually to perform any nesting with these environments, so why would you ever want to?

Unnestable Can't nest them. Can't nest into them.

- Chapter
- Section
- Subsection
- Subsubsection
- Paragraph
- Subparagraph
- Section*
- Subsection*
- Subsubsection*
- Bibliography
- Abstract
- Title
- L^AT_EX Title
- Author
- Date

Fully Nestable You can nest them. You can nest other things into them.

- Verse
- Quote
- Quotation
- Itemize
- Enumerate
- Description
- List
- LyX-Code

Nestable-Inside You can nest them inside of other things. You can't nest anything into them.

- Standard
- Right Address
- Address
- L^AT_EX

The **Caption** environment doesn't really fit anywhere, since it's only used inside of **Table Floats** and **Figure Floats**.

3.4.3 Nesting Other Things: Tables, Math, Floats, etc.

There are several things that aren't paragraph environments, but which are affected by nesting anyhow. They are:

- Equations
- Tables
- Figures

[Note: if you put a figure or a table in a **Float**, this is no longer true. See below or look in sections 4.4 or 4.5 for more info.]

LyX can treat these three objects as either a word or as a paragraph. Well, you can't inline a table, but you can inline math and figures. If a figure or an equation is inlined, it goes wherever the paragraph it's in goes.

On the other hand, if you have an equation, figure or table in a “paragraph” of its own, it behaves just like a “nestable-inside” paragraph environment. You can nest it into any environment, but you [obviously] can't nest anything into it.

Here's an example with a table:

1. Item One
 - (a) This is (a) and it's nested.

a	b
c	d

- (b) This is (b). The table is actually nested inside (a).

2. Back out again.

If we hadn't nested the table at all, the list would look like this:

1. Item One

- (a) This is (a) and it's nested.

a	b
c	d

1. This is (b). The table is *not* nested inside (a). In fact, it's not nested at all.

2. Back out again.

Notice how item (b) is not only no longer nested, but is also the first item of a new list!

There's another trap you can fall into: nesting the table, but not going deep enough. LyX turns anything after the table into a new [sub]list.

1. Item One

- (a) This is (a) and it's nested.

a	b
c	d

- (a) This is (b). The table is actually nested inside Item One, but *not* inside (a).

2. Back out again.

As you can see, item (b) turned into the first item of a new list, but a new list *inside* item 1. The same thing would have happened to a figure or an equation. So, if you nest tables, figures or equations, make sure you go to the right depth!

Then there are the so-called **FLOATS**. A **Float** is a block of text associated with some sort of label, but which doesn't have a fixed location. It can "float" forward or backward a page or two, to wherever it fits best. **Footnotes** and **Margin Notes** are floats, as are **Table Floats** and **Figure Floats**. When you're editing a document in LyX, a closed **Float** looks like a superscripted word in red and goes wherever the paragraph it's in goes. However, because a **Float** has not fixed location in the final text, nesting has no effect on its actual location after you feed your document to L^AT_EX.

3.4.4 Usage and General Features

3.4.4.1 The Various Bindings

Now that we've told you what you can and can't nest, it's about time we explained *how* to nest things!¹⁴

First, you have your choice of keybindings, a toolbar button, and a menu item. Selecting **Change Environment Depth** from the **Layout** menu *increases* the nesting depth by one level. You can also increase the depth by using the toolbar button showing a picture of a page, with two arrows on either side of an indented paragraph. Lastly, you can *increase* the nesting depth with the keybinding **M-p Right**, while **M-p Left** *decreases* the nesting depth.

There are two ways to nest text. You can select the text to nest, or you can simply move the cursor into the paragraph whose depth you want to change. The first method lets you alter several paragraphs at once.

Note that LyX only changes the nesting depth if it can. If it's invalid to do so, nothing happens if you try to change the depth. Additionally, if you change the depth of one paragraph, it affects the depth of every paragraph nested inside of it. It's hard to describe what exactly LyX does in this case. That depends specifically on what your text looks like. Your best bet is to simply play with changing the nesting depth and see what happens.

Lastly, we'd like to note the following:

¹⁴Author's Note: I debated putting this section before the previous two, but all three are so tied together, that it was hard to figure out the order. -jw

- If you *decrease* the depth multiple times [e.g. using M-p Left repeatedly] LyX stops at the outermost level.
- If you *increase* the depth multiple times [e.g. using M-p Right repeatedly] LyX “wraps around.” That is, when you reach the innermost level, LyX doesn’t stop there, but returns to the outermost level if you try to increase the depth once more.

Note that the “innermost level” does not mean the innermost possible depth. You can’t nest to an arbitrary level; there has to be something in the level above it.

Speaking of levels, LyX can perform up to a sixfold nesting. In other words, “level #6” is the innermost possible depth. Here’s an example to display what we mean:

1. level #1 - outermost
 - (a) level #2
 - i. level #3
 - A. level #4
 - level #5
 - level #6

Once again, LyX has a maximum of 6 levels, regardless of which specific paragraph environments you’re using at a given level.¹⁵ That means that you can perform a sixfold nesting of a **Description** list, or a **Verse** environment, and so on. You can also mix environments, as we shall see later.

There are two exceptions to the sixfold nesting limit, and you can see both of them in the example. Unlike the other fully-nestable environments, you can only perform a fourfold nesting with the **Enumerate** and **Itemize** environments. For example, if we tried to nest another **Enumerate** list inside of item “A.”, we’d get errors.¹⁶

¹⁵Unfortunately, LyX doesn’t enforce this limitation. If you try to exceed it, however, L^AT_EX will return errors when you go to produce output for your document.

¹⁶Once again, LyX doesn’t enforce this limitation. If you try to exceed it, however, L^AT_EX will return errors when you go to produce output for your document.

3.4.5 Some Examples

The best way to explain just what you can do with nesting is by illustration. We have several examples of nested environments. In them, we explain how we created the example, so that you can reproduce them.

3.4.5.1 Example #1: The Sixfold-Way and Mixed Nesting

#1-a This is the outermost level. It's a **List** environment.

#2-a This is level #2. We created it by using **M-Return** followed by **M-p Right**.

#3-a This is level #3. This time, we just hit **Return**, then used **M-p Right** twice in a row. We could have also created it the same way as we did the previous level, by hitting **M-Return** followed by **M-p Right**.

This is actually a **Standard** environment, nested inside of “#3-a”. So, it’s at level #4. We did this by hitting **M-Return**, then **M-p Right**, then changing the paragraph environment to **Standard**. Do this to create list items with more than one paragraph - it also works for the **Description**, **Enumerate**, and **Itemize** environments! Here’s another **Standard** paragraph, also at level #4, made with just a **M-Return**.

#4-a This is level #4. We hit **M-Return** and changed the paragraph environment back to **List**. Remember - we can’t nest anything inside of a **Standard** environment, which is why we’re still at level #4. However, we *can* keep nesting things inside of “#3-a”.

#5-a This is level #5...

#6-a ...and this is level #6. By now, you should know how we made these two.

#5-b Back to level #5. Just hit **M-Return** followed by a **M-p Left**.

#4-b After another **M-Return** followed by a **M-p Left**, we’re back at level #4.

#3-b Back to level #3. By now it should be obvious how we did this.

#2-b Back to level #2.

#1-b And last, back to the outermost level, #1. After this sentence, we'll hit **Return** and change the paragraph environment back to **Standard** to end the list.

There you have it! Oh — we could have also used the **Description**, **Quote**, **Quotation**, or even the **Verse** environment in place of the **List** environment. The example would have worked exactly the same.

3.4.5.2 Example #2: Inheritance

This is the LyX-Code environment, at level #1, the outermost level. Now we'll hit **Return**, then **M-p Right**, after which, we'll change to the **Enumerate** environment.

1. This is the **Enumerate** environment, at level #2.
2. Notice how the nested **Enumerate** not only inherits its margins from its parent environment [LyX-Code], but also inherits its font and spacing!

We ended this example by hitting **Return**. After that, we needed to reset the paragraph environment to **Standard** and resetting the nesting depth by using **M-p Left** once.

3.4.5.3 Example #3: Labels, Levels, and the **Enumerate** and **Itemize** Environments.

1. This is level #1, in an **Enumerate** paragraph environment. We're actually going to nest a bunch of these.
 - (a) This is level #2. We used **M-Return** followed by **M-p Right**. Now, what happens if we nest an **Itemize** environment inside of this one? It will be at level #3, but what will its label be? An asterisk?

- No! It's a bullet. This is the *first Itemize* environment, even though it's at level #3. So, its label is a bullet. [Note: we got here by using **M-Return**, then **M-p Right**, then changing the environment to **Itemize**.]
 - Here's level #4, produced using **M-Return**, then **M-p Right**. We'll do that again...
 - i. ...to get to level #5. This time, however, we also changed the paragraph environment back to **Enumerate**. Notice the type of numbering! It's *lowercase Roman*, because we're the *thirdfold Enumerate* environment [i.e. we're an **Enumerate** inside an **Enumerate** inside an **Enumerate**].
 - ii. What happens if we *don't* change the paragraph environment, but decrease the nesting depth? What type of numbering does LyX use?
 - iii. Oh, as if you couldn't guess by now, we're just using **M-Return** to keep the current environment and depth but create a new item.
 - iv. Let's use **M-p Left** to decrease the depth after the next **M-Return**.
 - i. This is level #4. Look what type of label LyX is using!
 - i. This is level #3. Even though we've changed levels, LyX is still using a lowercase Roman numeral as the label. Why?!
 - ii. Because, even though the nesting depth has changed, the paragraph is *still* a thirdfold **Enumerate** environment. Notice, however, that LyX *did* reset the counter for the label.
- (b) Another **M-Return M-p Left** sequence, and we're back to level #2. This time, we not only changed the nesting depth, but we also moved back into the twofold-nested **Enumerate** environment.
2. The same thing happens if we do another **M-Return M-p Left** sequence and return to level #1, the outermost level.

Lastly, we reset the environment to **Standard**. As you can see, the level number doesn't correspond to what type of labelling LyX uses for the **Enumerate** and **Itemize** environments. The number of *other Enumerate environments* surrounding it determines what kind of label LyX uses for an **Enumerate** item. The same rule applies for the **Itemize** environment, as well.

3.4.5.4 Example #4: Going Bonkers

1. We're going to go totally nuts now. We won't nest as deep as in the other examples, nor will we go into the same detail with how we did it. [level #1: Enumerate]

[Return, M-p Left, Standard: level #2] We'll stick an encapsulated description of how we created the example in brackets someplace. For example, the two keybindings are how we changed the depth. The environment name is, obviously, the name of the current environment. Either before or after this, we'll put in the level.

2. [Return, Enumerate: level #1] This is the next item in the list.

Now we'll add verse.

It will get much worse.

[Return, M-p Left, Verse: level #2]

Fiddle dee, Fiddle doo.

Bippitye boppitye boo!

[M-Return]

Here comes a table for you:

one-fish	two-fish
red-fish	blue-fish

[M-Return, Table, M-p Right 3 times, M-Return, Verse, M-p Left]

3. [Return, Enumerate: level #1] This is another item. Note that selecting a **Table** resets the nesting depth to level #1, so we increased the nesting depth 3 times to put the table inside the **Verse** environment.

We're now ending the **Enumerate** list and changing to **Quotation**. We're still at level #1. We want to show you some of the things you can do by mixing environments. The next set of paragraphs is a “quoted letter.” We'll nest both the **Address** and **Right Address** environments inside of this one, then use another nested **Quotation** for the letter body. We'll use **M-Return** to preserve the depth. Remember that you need to use **C-Return** to

create multiple lines inside the `Address` and `Right Address` environments. Here it goes:

1234 Nowhere Rd.
Moosegroin, MT 00100
9-6-96

Dear Mr. Fizlewitz:

We regret to inform you that we cannot fill your order for 50L of compressed methane gas due to circumstances beyond our control. Unfortunately, several of our cows have mysteriously exploded, creating a backlog in our orders for methane. We will place your name on the waiting list and try to fill your order as soon as possible. In the meantime, we thank you for your patience.

We do, however, now have a special on beef. If you are interested, please return the enclosed pricing and order form with your order, along with payment.

We thank you again for your patience.

Sincerely,

=====

That ends that example!

As you can see, nesting environments in LyX gives you a lot of power with just a few keystrokes. We could have easily nested an `Itemize` list inside of a `Quotation` or `Quote`, or put a `Quote` inside of an `Itemize` list. You have a huge variety of options at your disposal.

3.5 Fonts and Text Styles

3.5.1 Overview

Many modern typesetting and markup languages have begun to move towards specifying character styles rather than specifying a particular font.

For example, instead of changing to an italicized version of the current font to emphasize text, you use an “emphasized style” instead. This concept fits in perfectly with LyX. In LyX, you do things based on contexts, rather than focussing on typesetting details.

Right now, LyX allows you to specify a global default font, and has two character styles, **Emphasized** and **Noun**. The **Emphasized** style corresponds to an italics font. The **Noun** style corresponds to a font in smallcaps, which some languages and writing styles use to typeset proper names. The LyX Team actually hopes to someday have a full set of character styles, and to also allow the user to customize which font changes correspond to what styles. At the moment, though, you’ll have to be satisfied with what we’ve done already.

3.5.2 Global Options

You can set the default font from the Document Layout popup, activated using **Document...** from the Layout menu. There are two options of interest here, **Fonts** and **Font Size**. The possible options under **Fonts** include “default” and a list of fonts available on your system. The option “**default**” uses whatever you’ve specified as the default font in `system.lyxrc` or `{$HOME}.lyxrc`. Most systems will typically have some version of a Times and Helvetica font, with other variants. You’ll have to examine this for yourself.

As for the **Font Size** option, there are three possible values: 10, 11, and 12. Remember, this is the *default* font size. LyX acutally scales all of the other possible font sizes [such as those used in footnotes, superscripts, and subscripts] by this value. You can always fine-tune the font size from within the document if you need to. It’s also rather silly to use an 8pt or 24pt font as the default font size, as this typically renders your document unreadable.

Note that once you choose a new value for **Fonts** or **Font Size**, LyX does *not* change the screen. You’ll only see a difference once you generate the final output. This is part of the WYSIWYM concept. Besides, if you’re intelligent enough to use a computer, you’re intelligent enough to recognize that “Roman” text on the LyX screen corresponds to the default font.

3.5.3 Using Different Character Styles

As we’ve already seen, LyX automatically changes the character style for certain paragraph environments. We also mentioned two other character styles,

Emphasized and **Noun**. You can activate both of these styles via keybindings, the menus, and the toolbar.

To activate the **Noun** style, do one of the following:

- select **Noun Style** from the **Layout** menu
- click on the toolbar button with the person-shaped icon
- use the keybinding **M-c c**

These commands are all toggles. That is, if **Noun** style is already active, they deactivate it.

One typically uses the **Noun** style for proper names. For example: “MATTHIAS ETTRICH is the original author of LYX.”

A more widely used character style is the **Emphasized** style. You can activate [or deactivate - it’s also a toggle] the **Emphasized** style by:

- selecting **Emphasize Style** from the **Layout** menu
- clicking on the toolbar button with the “!” character on it
- using the keybindings **M-c e** or **M-c i**

At the moment, the **Emphasized** style is equivalent to an italicized font. We have plans to make that association more user-configurable in the future.

We’ve been using the **Emphasized** style all over the place in this document. Here’s one more example:

Don’t overuse character styles!

It’s also a warning in addition to an example. One’s writing should parallel ordinary conversation. Since we don’t all constantly scream at each other, we should also avoid the common tendency to overuse character style.

Oh — one last note: You can always reset to the default font using the keybinding **M-c Space**.

3.5.4 Fine-Tuning with the Character Layout Popup

There are always occasions when you'll need to do some fine-tuning, so LyX gives you a way to create custom character style. For example, an academic journal or a corporation may have a style sheet requiring a sans-serif font be used in certain situations.¹⁷ Also, writers sometimes use a different font to offset a character's thoughts from ordinary dialogue.

Before we document how to use custom character style, we want to issue a warning yet again: Don't overuse character styles. Many modern word processors have a vast array of fonts available to them, providing you with the power of a printing press. Unfortunately, there is this tendency to overuse that power. The phrase, "Using a sledgehammer to swat a fly," comes to mind. And, as the old saying implies, documents that overuse different fonts and sizes tend to look like someone's knocked huge holes in it.

Enough complaining.

To use custom fonts, open the Character Layout popup using Character... from the Layout menu. There are five buttons on this popup, each corresponding to a different font property which you can choose. You can choose an option for one of these five properties, or select No change, which keeps the current state of that property.

The five font properties, and their options [in addition to No change] are:

Family The "overall look" of the font. The possible options are:

- | | |
|------------|--|
| Roman | This is the Roman font family.
It's also the default family. [keybinding = M-c r] |
| Sans Serif | This is the Sans Serif font family.
[keybinding = M-c s] |
| Typewriter | This is the Typewriter font family.
[keybinding = M-c p] |

Series This corresponds to the print weight. Options are:

- | | |
|--------|--|
| Medium | This is the Medium font series.
It's also the default series. |
|--------|--|

¹⁷Note from JOHN WEISS: There is, in fact, such a style sheet for the LyX Documentation, since manuals need a certain amount of consistency.

Bold	This is the Bold font series. You can toggle this series on or off using Bold Style from the Layout menu, or with the keybinding M-c b .
Shape	As the name implies. Options are:
Up	This is the Up font shape. It's also the default shape.
Italic	<i>This is the Italic font shape.</i> Equivalent to the Emphasized character style.
Small caps	THIS IS THE SMALL CAPS FONT SHAPE. Equivalent to the Noun character style.
Size	Alters the size of the font. You'll find no numerical values here; all possible sizes are actually proportional to the default font size. Once again, you don't feed LyX the details, but a general description of what you want to do. The options [and their keybindings] are:
Tiny	This is the "Tiny" font size. [keybinding = M-s t or M-s 1]
Small	This is the "Small" font size. [keybinding = M-s s or M-s 2]
Normal	This is the "Normal" font size. It's also the default size. [keybinding = M-s n or M-s 3]
Large	This is the "Large" font size. [keybinding = M-s l or M-s 4]
Larger	This is the "Larger" font size. [keybinding = M-s S-L or M-s 5]
Largest	This is the "Largest" font size. [keybinding = M-s S-A or M-s 6]

- Huge This is the “Huge” font size.
 [keybinding = M-s h or M-s 7]
- Giant This is the “Giant” font size.
 [keybinding = M-s g or M-s S-H or M-s 8]

We’ll warn you *yet again*: don’t go crazy with this feature. You should almost never need to change the font size. LyX automatically changes the font size for different paragraph environments - use that instead. This is here for fine-tuning *only!*

Bar Whether or not to put a bar under the characters. Options are:

- No bar This is text with no bar.
 It’s also the default.
- Underbar This is text with Underbar on.
 [keybinding = M-c u]

Avoid using this if you can! It’s a holdover from the typewriter days, when you couldn’t change fonts. We no longer need to resort to emphasizing text by overstriking it with and underscore character. It’s only included in LyX because it’s also in L^AT_EX, and because some people *may* need it in order to follow style sheets for journal submissions.

You have a huge number of combinations to choose from.

Once you’ve chosen a new character style via the Character Layout popup, you can activate it using the toolbar button labelled “Font”. [You can, of course, also use the usual Ok and Apply buttons.] The toolbar button lets you toggle the state of your custom character style even when the Character Layout popup isn’t visible.

As we stated earlier, to completely reset the character style to the default, use M-c Space.

We conclude with the same warning we’ve been spewing: Don’t overuse the fonts. They are, more often than not, a kludge and a horrible substitute for good writing. Your writing should speak for itself - and will.

3.6 Printing and Previewing

3.6.1 Overview

Now that we've covered some of the basic features of document preparation using LyX, you probably want to know how to print out your masterpiece. Before we tell you that, however, we want to give you a quickie explanation of what goes on behind-the-scenes. We cover some of this information in sec. 5.1 as well.

LyX uses a program called “ \LaTeX ” as its backend. [Actually, \LaTeX is just a macro package for the \TeX typesetting system, but to prevent confusion, we'll just refer to the whole magilla as “ \LaTeX .”] Think of it this way: LyX is what you use to do your actual writing. Then, LyX calls \LaTeX to turn your writing into printable output. This happens in a couple of stages:

1. First, LyX converts your document to a series of text commands for \LaTeX , generating a file with the extension, “`.tex`”.
2. Next, \LaTeX uses the commands in the `.tex` file to produce printable output. It doesn't know anything about your printer, however. Instead, \LaTeX produces what's known as a *device-independent* file, or Dvi for short. The actual output is in a file with the extension, “`.dvi`”. Dvi files are completely portable; you can move them from one machine to another without needing to do any sort of conversion.

NOTE: The dvi-file only contains what was in the \LaTeX file itself. If you have included PostScript® pictures in your document, there will only be a link to these files. So don't forget these files if you move your `.dvi` file to another computer.

3. Consider the `.dvi` file to be the “final output.” Once you have it, you can view it, print it, or convert it to other formats.
 - (a) You can view `.dvi` files using a program called `xvvi`.
 - (b) Some printers and Unix systems understand Dvi, and can print your `.dvi` file directly.
 - (c) Nowadays, most printers understand the PostScript® format. LyX automatically converts the `.dvi` file to a PostScript® file for you

when you go to print out your document. LyX will also let you preview a PostScript® version of your document using the program *ghostview*.

One advantage of using PostScript® is that the converter program [called *dvips*] takes any PostScript® graphics you may have included in your document and puts it into the resulting PostScript® version of your document. It also includes any special fonts you may have used. That makes the PostScript® version much, much more portable than the Dvi version.

LyX does all of these steps automagically for you.

As you have seen, a lot of things happen before you get a hardcopy or a preview of your document. So, don't worry if printing requires a bit more time than with other word processors. The printed result is worth the wait. Quality always has its price.

3.6.2 Quick Viewing with *xdvi*

To get a look at the final version of your document, with all of the pagebreaks in place, the footnotes correctly numbered, and so on, select *View* (*xdvi*) from the *File* menu. Then wait a while.

When all of the behind-the-scenes action is done, LyX calls the program *xdvi*. You can now look at the results. [If you want more info on the *xdvi* program, see the *man-pages*.]

Helpful-Tip: Keep the *xdvi* window open, maybe moving it to another desktop. Then, after you make changes to your document, just use *Run L^AT_EX* from the *File* menu. Now click on the *xdvi* window. The *xdvi* program will automatically reread the *.dvi* file and give you an updated view.

3.6.3 Viewing the PostScript® Version with *ghostview*

In general, using *xdvi* to view your document is the easiest and fastest way. There may be times, however, when you want to look at the PostScript® version. One reason is fonts.¹⁸ You can use PostScript® fonts in a L^AT_EX

¹⁸Note from JOHN WEISS: Another reason is paranoia. I always like to look at the PostScript® file before I print it, just so I see exactly what went to the printer....

document, but `xdvi` won't show this. You'll need to use `ghostview` or some other PostScript® file viewer to see the actual results.

To view the PostScript® version of your document, select **View (ghostview)** from the **File** menu. Then go get some coffee.¹⁹ When all of the magic behind-the-scenes is done, LyX calls the program `ghostview`. You can now look at the results.

Unfortunately, it's not as easy to get an updated view with `ghostview` as it is with `xdvi`. You can *sort of* do it by printing to a file, then, on your own, viewing that file with `ghostview`. You can then re-print to the file and tell `ghostview` to reopen the file to update the view. This may be changed in future versions.

3.6.4 Printing the File

To print a file, select **Print...** from the **File** menu, or click on the toolbar button with the printer on it. This opens the **Print** popup.

Here's a list of what all of the different options do:

Print Three toggle buttons that determine which pages to print. You can choose:

- All Pages
- Only Odd Pages
- Only Even Pages

You can use these to print on both sides of a page even if your printer only prints single-sided. Just print the odd-numbered pages first, then turn the paper over and print the even-numbered pages.

Order Two toggle buttons that determine what order to print in. Some printers spit out pages face-up, others, face-down. By choosing a particular order, you can take the entire stack of pages out of the printer without needing to reorder them.

Print to: Two toggle buttons tied to text boxes. You can print to either a file or a printer:

¹⁹Note from MATTHIAS ZENKER: A reasonably fast machine will not let you the time, however...

Printer This is the name of the printer to print to.²⁰ The printer should understand PostScript® files.

File The name of a file to print to. The output will be in PostScript® format.

Be careful with this option, though. LyX currently uses a temporary directory to hold all of the different files that it generates. Unless you've disabled this feature, you need to specify the full path name for the output file. For example: “/home/me/docs/myfile.ps”. If you don't specify the full path name, LyX writes the file to the temporary directory.

Note that printing may need little time, since L^AT_EX, dvips and, if you don't have a PostScript printer, ghostscript have to process your document.

3.7 A Few Words about Typography

3.7.1 Hyphens and Hyphenation

In LyX, the “-“ character comes in three lengths, often called the *hyphen*, the *en dash*, and the *em dash*:

1. hyphen	-	made with “-“
2. en dash	-	made with “- -“
3. em dash	—	made with “- - -“
4. minus sign	-	a “-“ in math mode

You generate these by using the “-“ character multiple times in a row. LyX automatically converts them to the appropriate length dash in the final output.

²⁰Note that this printer name isn't for the lpr command but for dvips. That means dvips has to be configured for this printer name. See the section 2.6.2 or the dvips documentation for details. The default printer can also be set in \${HOME}.lyxrc and system.lyxrc.

The three types of dash are distinct from the minus sign, which appears in math mode and has a length of its own. Here are some examples of the “_” in use:

1. line- and page-breaks (hyphen)
2. From A–Z (en dash)
3. Oh — there’s a dash. (em dash)
4. $x^2 - y^2 = z^2$ (minus sign)

Those of you reading this from within LyX will see no difference, though there is one in the printed version.

One last note about hyphenation — LyX automagically breaks up words and inserts hyphens in English text. [Actually, it’s L^AT_EX that does this, and it will also hyphenate words in *some* other languages.] The words won’t be hyphenated until you generate the final output.

If, for some reason, L^AT_EX can’t break a word correctly, you can set hyphenation points manually. This is done with the menu item **Hyphenation Point** under **Special Characters** in the **Insert** menu. Note that these extra hyphenation points are only recommendations to L^AT_EX. If no hyphenation is necessary, L^AT_EX will totally ignore them.

3.7.2 Punctuation Marks

3.7.2.1 Abbreviations and End of Sentence

When LyX calls L^AT_EX to generate the final version of your document, L^AT_EX automatically distinguishes between words, sentences, and abbreviations. L^AT_EX then adds the “appropriate amount of space”: sentences get a little bit more space between the period and the next word. Abbreviations get the same amount of space after the period as a word uses.

Unfortunately, the algorithm for figuring out what’s an abbreviation and what’s the end of a sentence is really quite brain-dead. If a “.” is at the end of a lowercase word, it’s the end of a sentence; if it’s at the end of a capitalized word, it’s an abbreviation.

Here are some examples of *correct* abbreviations and the end of a sentence:

- Mr. Jones

- Don't worry. Be happy.

...and here's an example of the algorithm going wrong:

- e. g. this is too much space!
- Relax. It's okay.

You won't see anything wrong until you view a final version of your document.

To fix this problem, use one of the following:

1. Use a Protected Blank after lowercase abbreviations (see section 4.3.5).
2. Use the T_EX command “\@” at the end of a sentence, between the last word and the period.

Using a “\@” at the end of a sentence forces the use of inter-sentence spacing.

To mark text as T_EX commands, use the toolbar button labelled “T_EX” or the keybinding M-c t. (See section 5.3 for more info.)

With the corrections, our earlier examples look like this:

- e. g. this is too much space!
- Relax. It's okay.

Some languages don't use extra spacing between sentences. [You can set this inside of your \${HOME}.lyxrc or in the system.lyxrc file.] If your language doesn't use extra spacing between sentences, you don't need to worry about all of this.

3.7.2.2 Quotes

LyX usually sets quotes correctly. Specifically, it will use an opening quote at the beginning of quoted text, and use a closing quote at the end. For example, “open close”. The keyboard character, " ", generates this automatically.

You can change the behavior of the " key using the Quotes popup. Choose Quotes... from the Layout menu. Selecting the Double button makes the " key produce the sequence: “ ”. The Single button, in contrast, makes the " key produce: “ ”.

You can also select quotes for different languages via the Type option. there are three choices:

German Use German-style quotes: „double“ or ‚single‘

English Use English-style quotes: “double” or ‘single’

French Use the French guillemot: «double» or <single>

Again, this affects what character the " key produces.

On the other hand, if you want to produce a bona-fide quote character, type C-q. This produces: ".

3.7.3 Ligatures

It is standard typesetting practice to group certain letters together and print them as single characters. These groups are known as *ligatures*. Since L^AT_EX knows about ligatures, your LYX documents will contain them, too. Here are the possible ligatures:

- ff
- fi
- fl
- ffi
- ffl

Once in a while, though, you don't want a ligature in a word. While a ligature may be okay in the word, “graffiti,” it looks really weird in compound words, such as “cufflink” or the German “Dorffest.” To break a ligature, use the L^AT_EX command “\v” between the letters. [Use M-c t or the toolbar button labelled T_EX to mark text as L^AT_EX commands. See sec. 5.3.] This changes “cufflinks” to “cufflinks” and “Dorffest” to “Dorffest”.

3.7.4 Widows and Orphans

In the early days of word processors, page breaks went wherever the page happened to end. There was no regard for what was actually going on in the text. You may remember once printing out a document, only to find the heading for a new section printed at the very bottom of the page, the first

line of a new paragraph all alone at the bottom of a page, or the last line of a paragraph at the top of a new page. These dangly-bits of text became known as *widows* and *orphans*.

Clearly, LyX can avoid breaking pages after a section heading. That's part of the advantage of paragraph environments. But what about widows and orphans, where the page breaks leave one line of a paragraph all alone at the top or bottom of a page? There are rules built into L^AT_EX governing page breaks, and some of those rules are there to specifically prevent widows and orphans. This is the advantage LyX has in using L^AT_EX as its backend.

There's no way we can go into how T_EX and L^AT_EX decide to break a page, or how you can tweak that behavior. Some L^AT_EX books listed in the bibliography [such as [3] or [4]] may have more information. You will almost never need to worry about this, however.

3.8 A LyX Boo-Boo: Square Brackets, []

Note from JOHN WEISS:

There is a problem with square brackets, []. Unfortunately, LyX isn't passing these to L^AT_EX correctly, often resulting in erroneous L^AT_EX code.

You see, L^AT_EX *sometimes* uses “[]” to denote optional arguments to a L^AT_EX command. Now, you needn't worry about this. LyX typically takes care of all of that stuff for you. However, once in a while, L^AT_EX goofs, and thinks that your parenthetical remark is actually an argument to a command. Since there isn't a command there, or there isn't an argument inside the “[]”, L^AT_EX barfs and returns errors to you.

I've noticed problems in the following contexts:

- ...at the beginning of an item in an **Enumerate** or **Itemize** paragraph environment
- ...at the beginning of a **Standard** paragraph nested inside an **Enumerate** or **Itemize** environment
- ...immediately after a **Linebreak**, at the beginning of the next line.

There are three things you can do:

1. Don't use “[]”.
2. Don't put things in square brackets at the beginning of lines if you think it will cause trouble.
3. Put a Protected Blank at the beginning of lines, just before the “[”, if you think you'll have trouble.

To conclude, here are three cases where the stuff in the “[” would generate errors if the Protected Blank weren't there:

- [problem 1] This is a normal **Itemize** item.
[problem 2] This is a **Standard** nested inside of an **Itemize** environment.

This is **Verse**

[problem 3]

Things would be worse

Due to the line with the “[” up front

Since lines in a stanza inside of **Verse**

Use Linebreak to end a line.

[Editor's Note: Jean-Marc Lasgouttes has recently created a patch to fix this problem. It will completely disappear as of version 0.12.x. - jw]

Chapter 4

Additional Tools

4.1 Footnotes

[Ed. Note - I still need to edit this. -jpw]

Unlike other typesetting programs, LyX uses “foldable” floats instead of displaying its footnotes at the bottom of the screen or somewhere else in your text. When you insert **Insert** a **Footnote**, you’ll first see a red box with a label “foot” appearing within your text. This box is LyX’s representation of your footnote. You can enter your text into this box. If you click the “foot”-label, the box will “fold”. You can access it at a later time by clicking on the word “foot” written as a superscript in red in the text, thereby “unfolding” the footnote.¹ You will not see any numbers within LyX. You don’t need to worry about those, anyhow, because LyX does the numbering for you, as well as putting the footnote at the bottom of the correct page, when it processes your file. If you want to turn already existing text into a footnote, simply mark it and click on the footnote-icon in the menu-bar.

What LyX cannot do, yet, is take care of special needs like setting the footnote-numbering back to 1 after each section in the **article**-class or changing the counter-style. You’ll need to insert L^AT_EX commands like the following to achieve that:

Using `\setcounter{footnote}{0}` will set the counter back to 1.¹

The following command will change the numbering to small letters. Take

¹To close this footnote, click on the red box on the left side.

¹The counter has been set back to 1.

a look at the next footnote in your xdvi or ghostview:^b

The next command sets the counter-style back to default, i.e. \arabic.³

You can use \arabic, \roman, \Roman, \alph or \Alpha and others as counter-styles. Just replace the L^AT_EX command in the above example and re-run T_EX to see what those styles can do.

NOTE: A float in L^AT_EX and L_YX isn't a simple paragraph as with usual word processors. It is a complex text structure that may contain everything except floats. That means you use all the layouts inside a float, even figures and tables. You may not need this too often, but if you need it sometimes it is a neat feature.

If you're intending to use the spellchecker, remember that floats have to open to be checked. In order to open or close *all* footnotes (and margin notes), choose Edit -> Floats, Open All Footnotes/Margin Notes.

4.2 Margin Notes

[Ed. Note - I still need to edit this. -jpw]

Margin notes look and behave just like footnotes in L_YX. When you insert a margin note (Insert->Marginnote, M-i m, Button #6 from the right), you'll see a red box with a label "margin" appearing within your text: This box is L_YX's representation of your margin note. You can enter your text margin into this box. If you click the "margin"-label, the box will "fold", making an exclamation mark appear beside the line in which you inserted the margin note. You can access it at a later time by clicking on the word "margin" written as a superscript in red in the text, thereby "unfolding" the margin note.

As a default, L_YX uses 1,9 cm (0.75 inches) as \marginparwidth. This might not be what you're looking for, but as with footnotes, L_YX cannot yet do everything L^AT_EX has to offer. You might want to consult your L^AT_EX handbook for additional commands. Here are two examples:

The following command will make a vertical line appear alongside your text—great for „thumbing“: \marginpar{\rule[-10mm]{30mm}{5mm}}.

^bThis is an example for a footnote with alphabetic numbering.
Use \renewcommand{\thefootnote}{\alph{footnote}} to get this.

³Use \renewcommand{\thefootnote}{\arabic{footnote}} to set the counter-style back to L_YX's default, i.e. \arabic.

Check your dvi- or ghostview-output to see what the the following command does.

Right, it lets you insert a margin note on the “wrong” side of a two sided \reversemargin comment.

4.3 Manual Fine-Tuning

4.3.1 Extra Horizontal Space

HFills are a special LyX feature for adding extra space in a uniform fashion. An **HFill** is actually a variable length space, whose length always equals the remaining space between the left and right margins. If there is more than one **HFill** on a line, they divide the available space equally between themselves.

Note: if you put an **HFill** at the beginning of a line, and it’s *not* the first line in a paragraph, LyX ignores it. This prevents **HFill**s from accidentally being wrapped onto a new line.

HFills can be inserted with **Insert->Special Character->HFill**. Here a few examples what you can do with them:

This is on the left side

Left

Left

This is on the right

Right

Right

That was an example in the **Quote** environment. Here: :is one in a standard paragraph. It may or may not be apparent in the printed text, but it *is* sitting in-between the two “:“.

Remember that we said that an **HFill** always fills the remaining space between the margins? There may be more than one set of margins on a line. Here’s an example with the **List** environment.

one two :three four five six

The “:“ marks the beginning of the item. [There is actually a “hidden” **HFill** inside of the label of the **List** environment; it’s put at the end of the label automagically.] **HFill**s work similarly in other “multimargin” situations, like two-column mode.

4.3.2 Extra Vertical Space

To add extra vertical space above or below a paragraph, use Layout->Paragraph to open the Paragraph Layout popup.

[Editor's Note: I'm leaving this empty for now since this has changed in 0.11. -jw]*

We're not going to provide an example of a VFills, as it's a waste of paper. They work the same as any other type of filler, including HFills: they fill the remaining vertical space on a page with blank space. If there are several VFills on a page, they divide the remaining vertical space equally between themselves. You can therefore use VFills to center text on a page, or even place text 2/3 down a page, or 1/4, and so on.

4.3.3 Changing Paragraph Alignment

You can also change the paragraph alignment with the Paragraph Layout popup. There are four possibilities:

- Block
- Left
- Right
- Center

The default in most cases is block alignment, in which the inter-word spacing is variable and each line of a paragraph fills the region between the left and right margins. The other three alignments should be self-explanatory, and look like this:

This paragraph is right aligned,
this one is centered,

this one is left aligned.

In some paragraph environments, the default is something other than block alignment.

4.3.4 Forcing Page Breaks

If you don't like the way L^AT_EX does the page breaks in your document, you can force a pagebreak where you want one. In general, this will *not* be

necessary because L^AT_EX is good at pagebreaking, as was already mentioned in section 3.7.4.

So in general there is no need to use the option described below, and we *strongly* recommend *not* to use it until the text is *really* finished, and until you have checked in the preview to see if you *really* have to change the pagebreaking. *Only* in those cases, you can force a pagebreak above or below a paragraph in the Paragraph Layout popup by selecting **Pagebreak-Above** or **Below**.

You might want to use a pagebreak to ensure that a figure or table appears at the top of a page. This is, of course, the wrong way to do it. LYX gives you a way of automatically ensuring that your figures and tables appear at the top of a page [or the bottom, or on their own page] without having to worry about what precedes or follows your figure or table. See sections 4.4 and 4.5 and read about **FLOATS** to learn more.

4.3.5 Other Tools

This section describes briefly how some features well known by the L^AT_EX user can be generated with LYX.

- The protected blank: It is used to tell LYX (and L^AT_EX) not to break the line at that point. This may be necessary to avoid unlucky linebreaks, like in:

A good documentation should weight no more than 1 kg.

Obviously, it would be a good thing to put a protected blank between “1” and “kg”. A protected blank is set with **Insert->Special Character->Protected Blank** or with C-Space.

- The linebreak: You can force linebreaks within a paragraph by selecting **Insert->Special Character->Linebreak** or with C-Return. You should, however, not use this to correct L^AT_EX’s linebreaking, as L^AT_EX is *very* good at linebreaking ... (see section 4.3.4). There are, however, a number of situations where it is necessary to actively set a linebreak, e.g. in a poem or for an Address(see sections 3.3.5.1, 3.3.5.2 and 3.3.7.2).

- Horizontal lines above or below a paragraph: These can be useful for headlines. You get them in the Paragraph Layout popup. Here:

is one.

4.4 Figures and Imported Graphics

No document preparation system is complete without the ability to import graphics from other utilities into the document. In LyX, these are referred to as “figures” whether they are actually figures in the traditional sense or simply some kind of imported image. Encapsulated PostScript® figures are handled very well by LyX, which uses `ghostview` to generate an onscreen image for the LyX window, and the `\epsfig` L^AT_EX command to insert the figure in the final document.

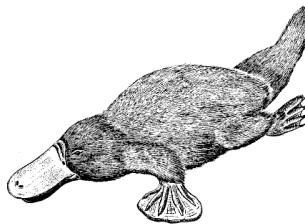

Note that figures referred to here are uncaptioned and sit wherever in the document you place them. If you need one of these features, see sec. 4.4.1.1 below.

Placing a figure in your document is done in two stages; first you tell LyX that you want a figure, then you open the blank figure and tell LyX the details about your figure. To place the figure, you click on the second right-most icon on the toolbar, or select **Insert->Figure...** from the menu.

You will be presented with a popup which contains three options:

Encapsulated Postscript: This is for inserting normal PostScript® figures.

The figures will sit between lines on their own, such as here:

Inlined EPS: This is for PostScript® figures as well, but these figures behave differently; they are inserted in the text stream like this tiny fellow.

LATEX or TEX: This is for LATEX or TEX figures, which can be inserted straight into LyX's LATEX output. Such figures can be produced manually, or by programs such as *xfig*. Use of these figures is simple: you enter the name of the file after the “\input” box which appears. Any fine-tuning should be done in the figure using LATEX, or inserting LATEX commands before the figure; there is no popup for manipulating the image, so this option will not be referred to again.

The second stage of manipulating a figure is done by double-clicking the left mouse button on the figure. *[This will be a single middle click in 0.12 I believe? - PR]* A dialog box will appear, which allows you to enter the filename and various other parameters. The changes you make will not be applied to the figure until you hit **Apply**.

This dialog has numerous parameters, so I'll step though each one in order.

EPS File: This is the filename, and is fairly self-explanatory. The **Browse...** button lets you wander through the file heirarchy in a graphical manner and select a file with your mouse.

Width: This section lets you manipulate the width of the image. “Default” indicates that the image size will be whatever the “EPS file” says it should be. However, you can alter the size by checking one of “cm”, “inches” or “% of Page” and entering a number in the box to the right of those checkboxes. I have found that LyX's on-screen approximation of how the image will appear is most accurate when the “% of Page” option is selected.

Height: This is similar to “Width” above. Note that if only *one* of either the width or the height is specified and the other is set to “Default” then the ratio of width to height is will be kept the same as the original image.

Extra Parameters: If you're a TEXnician, you can manipulate this and the **Angle** field to fine-tune the LATEX command used to insert the figure into the document. The **Update Command** button can be used to see the effect on the command used.

Display: You can tweak the way the figure is displayed in LyX (this does not effect how the image will appear in the printed document, only on your screen). You may find that selecting Do not display this figure will speed up the performance of LyX. LyX will just put an empty box in the document.

Options: This box contains two options which didn't fit anywhere else. Display Frame places a frame around the figure in the LyX window (but has no effect in the final document). The Do Translations checkbox does something wonderful, I am sure. I have no idea what it is though *[Help me out here - what's it do? - PR; Ed. Note-I'm not sure myself -jpw]*

Full Screen Preview: This option simply calls up ghostview to view the PostScript® figure in a window by itself. This can be useful for checking the figure outside of LyX.

4.4.1 Figure Floats

4.4.1.1 Using Figure Floats

The problem with inserting figures straight into your text is that they might make the pagination of your document extremely awkward. To suit the LyX mentality of automating such processes, you might find it preferable to use **Figure Floats**, which LyX (actually, L^AT_EX) is free to move about your document as it deems necessary for a good fit. In return, LyX automates the listing of these figures and allows you to place a caption on them, using the **Caption** environment explained in sec. 3.3.9.1.

To place a **Figure Float** simply select **Insert->Figure Float** from the menu bar. You will get a float without a figure in it; use the toolbar icon described above to insert the actual figure. It seems simple, but there is subtlety involved in the placement of the caption. If you prefer your caption to appear below the figure, then insert the **Figure** when the cursor is at the very start of the caption (or you can delete the caption and recreate it by selecting the **Caption** environment after the figure has been inserted). If the cursor is at the end of the caption when you insert the **Figure** then it will be inserted after the caption. Inserting in the middle of the caption—well, now we're just getting silly, as shown in figure 4.1.

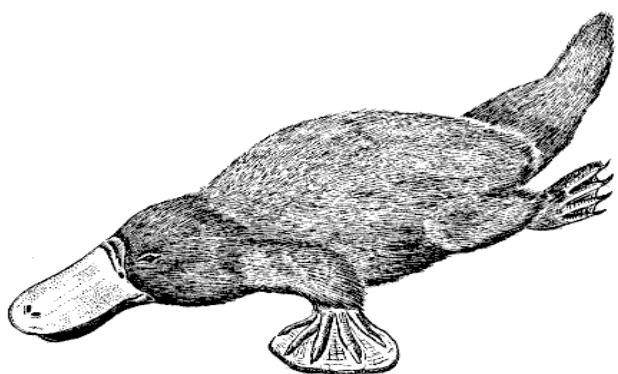

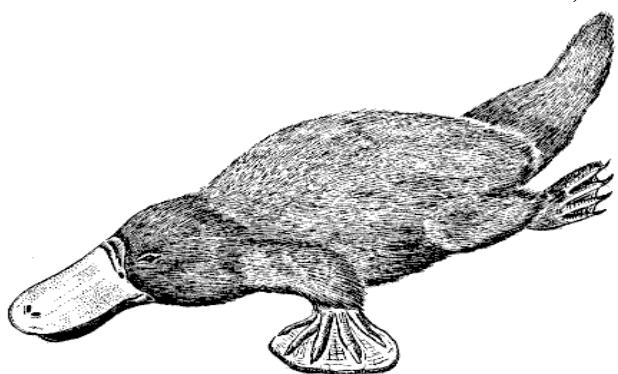

Figure 4.1: Mr. Plat E. Pus and his twin brother, in a float.

This figure also shows how we place a label and create a cross-reference to it; as you would expect from reading section 4.7 you can simply insert a Label in the caption and refer to it using a Cross-Reference as normal. It is especially important to use these with figure floats, rather than using vague references to “the above figure,” as L^AT_EX will reposition your floats for you in the final document; it might not be “above” at all. If it is not possible to fit the floats neatly on the same page as the text which refers to it (as is likely with a figure the size of Figure 4.1) the figures will be placed on a separate page by themselves. Rest assured that the overall effect is usually quite nice.

There are two more features of the Figure Float; the figure is automatically included in a List of Figures (as described in sec. 4.6.2) should you choose to include one in your document. The second feature is that (like all floats) it can be closed or opened, which lets you concentrate on your text and hide the figures.

4.4.1.2 Float Placement

Now, the whole idea behind Figure Floats [as well as Table Floats, which we introduce later] is to allow L_YX to place a figure [or table] on a page in a consistent, sensible fashion. This feature would be useless if you couldn’t control that “sensible fashion” in some way. L_YX has four different locations where it will try to put a figure:

Here: L_YX tries to put the Float at the same point in the text where you put it.

If there isn’t enough room, L_YX tries one of the other three location types.

Top: L_YX tries to put the Float at the top of the current page. If the figure won’t fit on the current page, it goes to the next page.

Bottom: L_YX tries to put the Float at the bottom of the current page. If there isn’t room, it goes to the next page.

Page: L_YX tries to put the Float on a page of its own.

You can specify this using the Document Layout popup [opened using Layout->Document]. There is a box called Float Placement which controls the global location of FLOATS.

Now, there is some subtlety to how this all works. You can place any combination of four letters in the **Float Placement** box, in any order:

- **h** for *here*
- **t** for *top*
- **b** for *bottom*
- **p** for *page*

The order specifies what location LyX should try first. If that one fails, it tries the next one, and so on. Here are some example entries and what they do:

1. **hbp**

Try putting the figure/table at its actual position in the text. If that doesn't work, put it on the bottom of the page. If that fails, put it on a separate page.

2. **tp**

Put the figure/table at the top of each page. If it's too long, put it on a separate page.

3. **p**

Always put figures and tables on their own page.

One last note: **Float Placement** controls the position of *both* figure and table floats.

4.4.2 XFig and LyX

One obvious question is “how would I create the figures?” Fortunately, the answer is included in most Linux and/or L^AT_EX distributions. **XFig** is a powerful and highly recommended drawing tool. If you want to include figures that you have created with **XFig** there are several ways. We recommend the following:

1. Export the figure as Encasulated PostScript®. This could be very easy included into LyX as described in the previous sections. The great advantage of this way is, that you have the full power of PostScript® available. That means bezier-curves, colors, all line thicknesses and many more. If you have inserted text into your fig-document this will be printed with PostScript® fonts, which is OK. The figure can be manipulated like any other EPS figure, as described above.

The only disadvantage is that you cannot create formulas as PostScript® text except by hand. If you also need formulas or simple exponents or indices in your figure, the next way is recommended.

2. Export the figure as LATEX. This is just as easy include into LyX, with the advantage that you may use all LATEX commands within the text inside XFig. Therefore you have to set the *special flag* for text in XFig. This is automatically if you invoke XFig with `xfig -specialtext`. If this is done and you have also chosen a LATEX font you may simply write “\$H_2\$” in XFig. If you export this figure as LATEX and include it in LyX with `\input` this text will appear as “ H_2 ”.

The disadvantage of this way is that the graphical power of LATEX isn’t as strong as PostScript®. You cannot use all thicknesses of lines and, more annoyingly, not all slopes. This is why we recommend the third way for more complex figures.

3. Export the figure as LATEX/PostScript® combined. Then XFig [transfig, really] will generate two files:

- (a) the PostScript® part `foo.ps_tex`, that contains all painting.
- (b) the LATEX part `foo.ps_tex_t`, that contains all text and a link to the PostScript® part.

Then you just have to include the LATEX part as described above with `\input foo.ps_tex_t`. This will automatically include the PostScript® part, too.⁴ This way you have the full PostScript® and LATEX-power combined except the possibility to scale the figure after creating. So if you like

⁴If you get an error like “unknown graphics extension ps_tex” you have to declare this graphic extensions. I think this is a transfig bug that occurs with LATEX2 ε . Simply add a line like

```
\@namedef{Gin@rule@ps_tex}{\rule{\ps_width}{\ps_height}}
```

scalable pictures the PostScript® format is your only choice. Another little advantage of letting L^AT_EX typeset the font is that the same font will appear in your figures as in your text, which looks a little nicer.

4.5 Tables

See the note for the Figures section.

Editor's Note - LyX can now display WYSIWYG tables! This entire section needs to be rewritten in the next pass of the Documentation Update!
-jw

As the note above indicates, this section has recently been rewritten to reflect a new feature: WYSIWYG tables. Now, L^AT_EX can do many, many more things with tables than LyX is currently capable of, so you might want to look at a good L^AT_EX book if the table feature described here is inadequate for your needs.

You can insert a table using either the table button or *Table->Insert Table...* from the *Edit* menu. A popup will appear, asking you for the number of rows and columns. The default table has lines at the top and to the left of every cell, a line to the right of the rightmost column and a line at the bottom of the lowest row, forming a box around the table. Additionally, the topmost row also has a line at the bottom, which causes this row to appear separated from the rest of the table. Here's an example:

	12	45	98
A			
B		multi	
C			

You can alter the table by clicking on it with the rightmost mouse button, which brings up a menu of options. Among these options are:

- Adding/removing lines from a row or column

in the file `/usr/lib/texmf/tex/latex/graphics/dvips.def`. Then add `ps_tex` to the extension:

```
\def\Gin@extensions{eps, ps, ps_tex, eps.gz, ps.gz, eps=2EZ}
```

This should fix the whole thing. Alternatively you may export the postscript part as `foo.eps` and change the latex part `foo.ps_tex_t` manually. But this is annoying.

- Text alignment in a cell
- Appending rows and columns
- Deleting rows, columns, or the entire table
- Multicolumn

When you append a row, it is added **below** the row containing the cursor. Similarly, columns are appended to the **right** of the cursor. Deletion is always performed on the row or column containing the cursor. Multicolumn merges two adjacent cells on a given row. For example, in the above table, row “B” has had multicolumn applied to the columns labelled “45” and “98.” To use it, you must first select the cells, then choose *Multicolumn* from the menu.

4.6 Table of Contents

[Ed. Note - I still need to edit this. -jpw]

One of the really nice features of L^AT_EX is the ease with which it lets you create various Lists like, e.g., a ToC (Table of Contents). All you need to do is to use certain environments and insert a reference at the place where you want the list to appear. You’ll also—this is important, because it is not self-explanatory—need to run L^AT_EX *twice* before you can view the final output. This is because of the way L^AT_EX creates Lists: When you run L^AT_EX on a document, e.g. to preview it in xdvi, you only run it *once*—which is perfectly allright for previewing text. In order for Lists (and some other stuff, too)—check [section with captions, bibliography] to appear, you need to run L^AT_EX one or two times more, in order for the information taht L^AT_EX has gathered in the first run to take effect. Think of the way the lists are made by yourself: First, you make “mental notes” which in which parts of your text the passages which are to appear in, say, your ToC are located; then, you write the ToC down. That’s just what L^AT_EX does: In its first run it checks where the entries are (creating a temporary file, for example `foo.toc` for the table of contents), then it creates the ToC. When you’re reading the dvi-output of this User Guide and you didn’t get a ToC or other lists, cross-indices, etc., rerun L^AT_EX and touch your xdvi with your mouse in order for the changes to take effect. Keep in mind, though, that the printed table of contents is always one version of your document older than the text.

So make sure that you do at least two L^AT_EX runs (with labels and references we recommend three) before you do your final print.

4.6.1 The Table of Contents

In order to get a Table of Contents (ToC), you need to do 5 things:

1. Use a document-class that supports ToC (i.e. all but letter).
 - (a) Use styles that are supported by the ToC function: Chapter, (Sub...) Section, (Sub...) Paragraph. Note that styles with a *, like section*, will *not* appear in the ToC.
 - (b) Make sure you set the Sec. Num. Depth and TOC. Depth to the appropriate value. If, for example, you only want chapters and sections to appear in the ToC, set the value to 3.
 - (c) Insert the ToC- command at a place of your liking. You'll find it under Insert -> Lists & TOC, Table of Contents.
 - (d) Make sure to run L^AT_EX *twice* in order for the ToC to appear in your dvi-output.

But there is something else that you can do with a ToC. If you're reading this document within LyX, you'll already have noticed that you get a second window with a ToC that lets you navigate the text. Once you've created a ToC in your text, you can invoke this function from Edit -> Table of Contents.

4.6.2 List of Figures and List of Tables

In order to get a Lists of Figures and Lists of Tables are much like ToCs. There are some slight differences, though, that you need to heed.

1. If you want your lists and figures to appear in your LoF or LoT, you'll need to use figure/table floats. You can find them under Insert -> Figure Float and Insert -> Table Float.
 - (a) Insert the LoF/LoT- command at a place of your liking. You'll find it under Insert -> Lists & TOC, List of Figures or List of Tables, respectively.
 - (b) Make sure to run L^AT_EX *twice* in order for the LoF/LoT to appear in your dvi-output.

4.7 Cross-References

[Ed. Note - I still need to edit this. -jpw]

Speaking of Cross-References... Here's one: Properly speaking, it is one half of a Cross-Reference, namely the Label. The other half is the Cross-Reference proper, and it looks like this: 4.7. What does a Cross-Reference do, then? Well, if you had a look at your dvi-output now, you would see that where you have the red-on-gray box in LyX, you have the number of chapter/section/etc., where you had inserted the label. Next, compare this Cross-Reference with your dvi-output: 95. Now, there is the number of your page on which you've inserted the label. So that's what Cross-References do: they let you reference other parts of your document. Labels are used as "anchors" and Cross-References check for these anchors and replace themselves with the information the anchor gives them.

In order for you to create Cross-References, you need to do both, insert a label in the place you want referenced, and a Cross-Reference in the place where the reference is to appear later. That's all. You'll find Labels Insert -> Label under and Cross-References under Insert -> Cross Reference. The Cross-Reference popup will let you choose whether you want a `\ref` or a `\pageref`. Note that if you cut & paste text from another document that contains a Label or Cross-Reference, or if you delete either one in your text, L^AT_EX will complain about something like his:

L^AT_EX Warning: Reference 'X' on page Y undefined on input line Z.

L^AT_EX Warning: There were undefined references.

You'll also see two question marks instead of the reference.

As of v0.10.7, Cross-References work with the math editor. See section 6.4 for more details.

4.8 WARNING WARNING WARNING

Got your attention, did we? Good.

To use any of the things described in sections 4.6-4.7, you *must* run L^AT_EX on your document more than once. You can do that using File->Run L^AT_EX [or its keyboard accelerator, M-f r] multiple times. For a Table of Contents or Cross-References and Labels, you'll need to run L^AT_EX *twice*.

You also need to run L^AT_EX on your document multiple times if you use a bibliography in your document. In fact, bibliographies generated by BiB^TE_X require *three* runs.

So how can you tell if you need to run L^AT_EX more than once? Simple: L^AT_EX will spit out warning messages that look like similar to this:

L^AT_EX Warning: Reference ‘X’ on page Y undefined on input
line Z.

L^AT_EX Warning: There were undefined references.

It’s a good idea to run LyX from an xterm so that you can see these messages. [Under Linux, if you run LyX from a menu, like those found in FWM, all of the messages from running L^AT_EX end up on the console.]

Someday, LyX will be able to do these multiple runs on its own. Until then, you’ll need to do it by hand.

Chapter 5

LyX and LATEX

5.1 How LyX Uses LATEX

This chapter is for both TEXperts and the LATEX-curious. In it, we'll explain how LyX and LATEX work together to produce printable output. This is the only place in any of the manuals where we assume you know something about LATEX.

At one time, we called LyX a “WYSIWYM frontend to LATEX,” but that's no longer true. There are frontends to LATEX out there. They are basically editors with the ability to run LATEX and mark any errors in the file you're editing. Although LyX *is* an editor, and it *does* run LATEX, and it also marks errors in the file, it also does much, much more. Thanks to the WYSIWYM concept,¹ you don't need LATEX to use LyX effectively. LyX has also added a few extensions to LATEX.² Try the following sometime: select **Make (nice) LATEX File** from the **File** menu, then look at the preamble of the resulting **.tex** file. You'll notice a variety of new macros defined specifically by LyX.³ This is all transparent to the user, however.

There are four commands that automatically invoke LATEX. They are:

- **Run LATEX**

¹What You See Is What You Mean

²The Team did this for parsing/coding reasons. The new macros allow LyX to more easily produce LATEX code and ensure that the resulting code is correct. Nothing that you, the user, need worry about

³A little bit of history: at one time, all of these macros were in a **lyx.sty** file. The Team has since decided that **.tex** files generated by LyX should be more portable. So, now the macros are in the preamble.

- View (xdvi)
- View (ghostview)
- Print...

All of these are in the **File** menu. The Run **LATEX** command will always invoke **LATEX**. The other three will only invoke **LATEX** if the file has changed since the last time **LATEX** was run.

When you run **LATEX** on the file you're editing, **LyX** performs these steps:

1. Save the current document (as **.lyx.bak!**).⁴
2. Convert the document to **LATEX** and save to a file with the extension **.tex** in place of **.lyx**.
3. Run **LATEX** on the **.tex** file.
4. If there are any errors, mark them in the document.

If you've run **LATEX** using **View (xdvi)**, **LyX** then executes **xdvi** on the **Dvi** file. If you've used **View (ghostview)** or **Print...**, **LyX** performs two more steps:

- Run **dvips** to convert the **Dvi** file to PostScript®:
 - For **View (ghostview)**, the output file has the extension **.ps_tmp**
 - For **Print...**, the output file has the extension **.ps**, as expected.
- Execute **ghostview** or send the PostScript® file to the printer.

LyX will only run **LATEX** once. It can't rerun **LATEX** if a second pass is needed - *yet*.

⁴Note from MATTHIAS ZENKER: I don't know why, but this is what happens. So your **.lyx** - document is *not* saved !

5.2 “Help! LyX generated an unreadable .tex file!”

Die-hard L^AT_EX users will scream and howl this into the night, then declare LyX useless, simply because they didn’t RTFM.⁵

We’re going to set the record straight. LyX produces two kinds of L^AT_EX files. One is human readable. The other is LyX readable. Every time LyX executes L^AT_EX, it produces a L^AT_EX file that it can easily scan for errors. The resulting .tex file is not human readable. Don’t even try to read it. If you want a .tex file that you can send to a colleague, select Make (nice) L^AT_EX File from the File menu.

We’ll say that again, specially separated for the particularly clue-impaired:

If you want a .tex file that you can send to a colleague, select Make (nice) L^AT_EX File from the File menu.

You should then rename that .tex file so that LyX doesn’t overwrite it.

5.3 Inserting L^AT_EX Code into LyX Documents

This is a rather important point: You can always insert L^AT_EX code into any LyX document. LyX simply cannot, and will probably never be able to, display every possible L^AT_EX construction. If ever you need to insert L^AT_EX commands into your LyX document, you have two options:

Inline: Mark a block of text as L^AT_EX anywhere, anytime.

- There are three ways to access this command:
 - Menu: Layout->L^AT_EX Style
 - Toolbar Button: The button with the red word “L^AT_EX” on it.
 - Keybinding: M-c t

⁵Note from JOHN WEISS: I know a certain faculty member who actually did complain to me that LyX doesn’t generate L^AT_EX files. Ain’t it funny how, sometimes, faculty are the worst at reading instructions?

It works just like a character style. You can toggle TeX Style on or off. When on, everything you type will be in TeX mode. You can also select a block of text and [for example] hit the TeX button to mark it as TeX code.

- Best used for brief or small bits of LATEX code.

We've already encountered some of the uses of TeX Style in sections 3.7.2.1 and 3.7.3.

LATEX Environment: We've already encountered this one, too, in section 3.3.9.3.

- The LATEX paragraph environment is for large blocks of LATEX code. Using it is pretty simple if you follow a guideline or two:

- Break lines using C-Return. A plain Return will reset the paragraph environment to Standard.
- Don't begin lines with a Space. LyX has a bug that gags on such lines. [I know, that means you can't indent your LATEX code to make it look pretty.]
- You *CAN* nest the LATEX environment inside of others. For example, suppose you wanted to do the following:

```
\begin{itemize}
\item ....
.
.
.
%Your LATEX Code to do something
%
.
.
.
\end{itemize}
```

You can just nest a LATEX environment inside of an Itemize environment to achieve the same thing.

- Here's an example of code in the LATEX paragraph environment. The code looks like this:

```
\begin{tabular}{ll}
\begin{minipage}{5cm}
This is an example for a minipage environment.
You can put nearly everything in it, even
(non-floating) figures and tables.
\end{minipage}
&
\begin{minipage}{5cm}
\begin{verbatim}
\begin{minipage}{5cm}
This ...
\end{minipage}
\end{verbatim}
\end{minipage}
\end{tabular}
```

What follows is the \LaTeX environment proper. Those of you reading the manual online will only see a bunch of funky text in red. Those reading a printed version of the manuals will see the actual results:

This is an example for a
minipage environment. You \begin{minipage}{5cm}
can put nearly everything in This ...
it, even (non-floating) fig- \end{minipage}
ures and tables.

In addition to these two methods, you can also create a separate file containing some complex \LaTeX structure. You can then use either the \TeX Style or the \LaTeX paragraph environment to put the \LaTeX command “`\input{myfile}`” into your document. \LaTeX will then include the file “`myfile.tex`” [note the addition of the “`.tex`” suffix] into your document. We recommend that you only do this if you have a `.tex` file which you *know* works already. Otherwise, you’ll have a big job tracking down \LaTeX errors....

There are a few last notes to emphasize:

- Inside of LyX, \LaTeX code appears *in red*.
- LyX *does not* check if your \LaTeX code is correct.
- Beware reinventing the wheel.

That last note refers to two things. First, LyX does have quite a few features tucked into it, and more are coming. Be sure to check the manuals to make sure that LyX doesn't have such-and-such feature before you go off merrily coding LATEX.⁶ Second, there are numerous LATEX packages out there to do all sorts of things, from labels to envelopes to fancy multipage tables. Check out a CTAN site for details.

If you do need to do some wild and fancy things within your document, be sure to check out a good LATEX book for assistance. There are a number of them listed in the bibliography of this manual.

There are a number of LATEX commands which have to be placed before the beginning of the actual text. They go into the preamble, and this is explained in the next section.

5.4 LYX and the LATEX Preamble

5.4.1 About the LATEX Preamble

If you already know LATEX, there is no need to explain here what the preamble is good for. If you don't, the following will give you some ideas — we recommend again that you consult a LATEX book for further information. In any case, you should read the points below, because they explain what you can do and what you don't need to do in the LATEX preamble of a LyX document.

The LATEX preamble comes at the very beginning of a document, *before* the text. It serves to:

- declare the document class. LyX already does this for you.

If you're a seasoned LATEX-er, and you have some custom document class you want to use, check out the *Customization Manual* for info how to make LyX interface to it. Be sure to submit your efforts to the LyX Team for inclusion in future versions!

- declare the usage of packages. LATEX packages provide special commands, which are only available within a document when the package has been declared in the preamble. For example, the package

⁶Note from JOHN WEISS: I seem to do this an awful lot. Sat down and merrily began coding something to print out labels, only to learn that there were already 2 different LATEX packages to do this. Worse yet - I had them already!

`indentfirst` forces all paragraphs to be indented. There are other packages for labels, envelopes, margins, etc.

- set counters, variables, lengths and widths. There are several L^AT_EX counters and variables which *must* be set globally from within the preamble in order to have the desired effect. [There are other variables which you can set and reset inside the document, too.] Margins are a good example of something which must be set in the preamble. Another example is the label format for lists. You can actually set these just about anywhere, but it's best to do it just once, inside the preamble.
- declare user defined commands [with `\newcommand` or `\renewcommand`], mostly abbreviations for L^AT_EX commands which appear very often inside a document. Although the preamble is a good place to declare such commands, they *can* be declared anywhere else [but *before* they are used for the first time, of course...]. This can be useful if there is a lot of raw L^AT_EX code in your document, which normally should not be the case.

LyX adds its own set of definitions to the preamble of the `.tex` file it produces. This makes L^AT_EX files generated by LyX portable.

5.4.2 Changing the Preamble

The commands which LyX adds to the preamble of a L^AT_EX file are fixed; you can't change them without patching LyX itself. You can, however, add your own stuff to the preamble. There are two ways to do this:

1. Select L^AT_EX preamble from the Layout menu. This opens an editing popup in which you can put your favorite commands.

The editing behavior of this popup is toolkit-dependent, so don't expect the LyX keybindings to work in it. In version 0.10.7, there is also no scrollbar. Sorry about that, but we're afraid you're stuck if your preamble is very long. We hope to add a scrollbar in a future version.

2. Add your favorite declarations and commands to your `.lyxrc` file. See the *Customization Manual* for additional info.

LyX adds anything in the **LATEX preamble** popup to its own built-in preamble. The same goes for things in the preamble section of the `.lyxrc` file, with one notable exception: LyX adds the preamble commands in `.lyxrc` to *every file's preamble*.

Before adding your own declarations in the preamble, you should make sure that LyX doesn't already support what you want to do [remember what we said about reinventing the wheel?]. Also *make sure your preamble code is correct*. LyX doesn't check it.

5.4.3 Examples

Here are some examples of what you can add to a preamble, and what they do:

5.4.3.1 Example #1: Offsets

There are two variables under LATEX that control page position: `\hoffset` and `\voffset`. Their names should be self-explanatory. These variables are useful if you think for a moment about computer labels. Sometimes, the size of a print medium and the area of the medium that you can actually print on aren't the same. This is where `\hoffset` and `\voffset` come in.

The default values for `\hoffset` and `\voffset` are both 0 pt., i. e. the page isn't shifted.

Unfortunately, some DVI drivers always seem to shift the page. We have no idea why, or why the sysadmin hasn't fixed such behavior. If you're using LyX on a system that you don't personally maintain, and your sysadmin is a doofus, `\hoffset` and `\voffset` can save the day. Suppose you're left and top margins are always 0.5 inches too big. You can add this to the preamble:

```
\setlength{\hoffset}{-0.5 in}
\setlength{\voffset}{-0.5 in}
```

...and your margins should now be correct.

5.4.3.2 Example #2: Labels

Speaking of labels, suppose you wanted to print out a bunch of address labels. There's a rather nice package, available at your nearest CTAN archive, for printing sheets of labels, called `labels.sty`. Now, your system may not have

this package installed by default. We leave that up to you to check. You'll also want to read the documentation for it; we're not going to do that for you. Since this is an example, however, we'll give you an example of how you use this package.

First, make sure you're using the `article` document class. Next, you need to put the following in your preamble:

```
\usepackage{labels}
\LabelCols=3
\LabelRows=7
\LeftBorder=8mm
\RightBorder=8mm
\TopBorder=9mm
\BottomBorder=2mm
```

This sets things up for Avery® label sheets, stock #5360. You're now ready to print labels, but you'll need to insert L^AT_EX code, placing the commands `\begin{labels}` and `\end{labels}` around each label text. This and other special features of `labels.sty` are explained in its documentation.

Someday, someone may write a LYX layout file to support this package directly. Maybe that someone is you.

5.4.3.3 Example #3: Paragraph Indentation

Americans are all trained to indent the first line of *every* paragraph. As with all of their other weird quirks, most Americans will whine and moan until they can have their way and indent the first line of all paragraphs.⁷

Of course, this behavior isn't standard typography. In books, you typically only indent the first line of a paragraph *if* it follows another one. The idea behind indenting the first line of a paragraph is to distinguish neighboring paragraphs from one another. If there is no previous paragraph, for example, it follows a figure, or is the first paragraph in a section, then there is no special indentation.

If you're a typical American, though, you don't care about such esoteric things; you want your indentation! Add this to the preamble:

⁷Note from JOHN WEISS: This was written by an American — *me!* It's my perception of my fellow countrymen. Tough if you don't like it. Thpbpbpbpbpbpbpb!

```
\usepackage{indentfirst}
```

If your TeX distribution isn't a braindead one, you'll have this package, and all of your paragraphs will get the indentation you think they deserve.

5.4.3.4 Example #4: Numbering in the Enumerate Paragraph Environment

The default numbering for the Enumerate paragraph environment begins with arabic numbers and ends with uppercase letters. Suppose, however, you wanted a different type of numbering scheme. As promised, we'll now describe how to do that.

Here's a quickie example of how to change the numbering scheme:

```
\renewcommand{\labelenumi}{\Roman{enumi}.}
\renewcommand{\labelenumii}{\Alpha{enumii}.}
\renewcommand{\labelenumiii}{\arabic{enumiii}.}
\renewcommand{\labelenumiv}{\alpha{enumiv}.})}
```

...which changes the numbering scheme to uppercase roman numerals, uppercase letters, arabic numbers, and lowercase letter.

Additionally, the previous example also adds a little bit extra to the numbering scheme. For example, the first level label actually looks like: "I.". For ease of reading, we'll describe what the numbering schemes look like using a notation something like this: <"I.", "A.", "1.", "a.")>.

As you can see in the example, there is a label command for each nesting level, \labelenumi ... \labelenumiv, as well as a counter, enumi ... enumiv. There are also five "number printing" commands, \arabic{}, \roman{}, \Roman{}, \alph{}, and \Alpha{}, each of which take one counter as an argument. You can add characters before or after these, but there's no need to add spaces.

You can get really fancy with these. For example:

```
\renewcommand{\labelenumi}{#\Alpha{enumi}#}
\renewcommand{\labelenumii}{\Alpha{enumi}.\arabic{enumii}}
\renewcommand{\labelenumiii}{\alpha{enumiii}+}
\renewcommand{\labelenumiv}{(\roman{enumiv})}}
```

produces the somewhat out of hand numbering scheme: <“#A#”, “A.1”, “a+”, “(i)”>.

As with all preamble commands, none of this shows up in LyX, which is only WYSIWYM, but will be in the final output. It’s up to you to make sure that your preamble code has the desired effect.

5.4.3.5 Example #5: This Document

You can also check out the preamble of this document to get an idea of some of the advanced things you can do. You’ll probably need to make the L^AT_EX preamble popup full-screen to see most of it.

5.4.3.6 Last Example: Margins

Editor’s Note: This example will disappear as of v0.12, when true margin support appears. I’ll also add documentation for margin support elsewhere at that time. -jpw

Every page has four margins, the left, the right, the top, and the bottom, right? Wrong. What about footnotes? How do you take those into account? What about page numbers, or headers?

As you can see, setting the margins for a document can be a tricky problem. Fortunately for us, some L^AT_EX-ers have made nice packages to handle all of this for us, namely `vmargin.sty` and `geometry.sty`.

Direct support for margin control is coming in v0.12. Right now, you’ll have to be satisfied with using one of the above packages.

Here’s an example preamble that uses the `geometry.sty` package and creates 1-inch margins on US-Letter paper:

```
\usepackage{geometry}
\geometry{letterpaper, left=1 in, right= 1in,
          top=1 in, bottom = 1 in}
```

If you are unlucky and don’t have `geometry.sty` on your system, this preamble fragment will do something similar:

```
\setlength{\oddsidemargin}{1 in}
\setlength{\evensidemargin}{1 in}
\setlength{\marginparwidth}{0.75 in}
\setlength{\marginparsep}{0.125 in}
\setlength{\topmargin}{0.5 in}
```

```
\setlength{\headheight}{0.25 in}
\setlength{\headsep}{0.25 in}
\setlength{\textwidth}{6.5 true in}
\setlength{\textheight}{9.0 true in}
```

Yeah, it's a mess.

5.5 LYX and LATEX Errors

When LYX calls LATEX, it tells LATEX to blithely ignore any errors and keep going. It then uses the log-file from the LATEX run to do a post-mortem. As we stated earlier in the chapter, LYX generates two kinds of .tex files, one of which it uses to locate errors in the document. If there was an error someplace, LYX will put a box with the word “Error” at the appropriate place in the document.⁸ It will also display a message popup alerting you to the fact that there were errors.

You can navigate through the errors by using Go to Error in the Edit menu. You can “open” the error-boxes and view the error message LATEX produced by double-clicking on it.

Some folks also like to look at the log file directly, or look at the xterm from which they ran LYX, which will also contain the output generated by any LATEX runs. There are some fairly common error messages and warnings. We’ll cover those here. You should look at a good LATEX book for a complete listing.

- “LATEX Warning:”

Anything beginning with these words is a warning message for the purpose of “debugging” the LATEX code itself. You’ll get messages like this if you added or changed cross-references or bibliography entries, in which case, LATEX is trying to tell you that you need to make another run.

You can by-and-large ignore these.

- “LATEX Font Warning:”

⁸LYX will occasionally misguess where the error was. This will typically happen with tables, figures, math, and the preamble.

Another warning message, this time about fonts which L^AT_EX couldn't find. The rest of the message will often say something about a replacement font that L^AT_EX used.

You can safely ignore these.

- “Overfull \hbox”

L^AT_EX absolutely *loves* to spew these out. They are warning you about lines that were too long and run past the right margin. Almost always, this is unnoticeable in the final output. Or, only one or two characters extend past the margin. L^AT_EX seems to generate at least one of these messages for just about any document you write.

You can ignore these stupid messages. Your eyes will tell you if there's a problem with something that's too wide; just look at the output.

- “Underfull \hbox”

Not quite as common as its cousin. L^AT_EX seems to like to print lines that are a bit too wide as opposed to ones that are a bit too narrow. We have no idea why.

You can ignore these, too.

- “Overfull \vbox” and “Underfull \vbox”

Warnings about troubles breaking the page. Once again, just look at the output. Your eyes will tell you where something has gone wrong.

- “~~L_EX~~ Error: File ‘Xxxx’ not found”

The file “Xxxx” isn't installed on this system. This usually appears because some package your document needs isn't installed. If you didn't touch the preamble or didn't use the \usepackage{} command, then one of the packages LyX tried to load is missing. Here are some common ones that may be missing:

1. `a4.sty`, `a4wide.sty` for different A4 paper sizes - only if you use them.
2. `inputenc.sty` for keyboard support
3. `babel.sty` for different language support

4. `epsfig.sty` for figures. This package will also need `graphics.sty` and `graphix.sty`. You will not be able to include postscript figures without it.

You should have the three last packages, since they generally come with the L^AT_EX 2_< distribution.

If you *did* use the `\usepackage{}` command, and the package in question isn't installed, you'll need to install it yourself.

- “`\TeX` Error: Unknown option”

Error messages beginning with this are trying to tell you that you specified a bad or undefined option to a package. Check the package's documentation.

- “Undefined control sequence”

If you've inserted L^AT_EX code into your document, but made a typo, you'll get one of these. You may have forgotten to load a package. In any case, this error message usually means that you used an undefined command.

There are other error and warning messages. Some are self-explanatory. These are usually L^AT_EX messages. Others are downright cryptic. These are actually T_EX error messages, and we really have *no clue* what they mean or how to decipher them.

There's a general sequence you should follow if you get error messages:

1. Look at the L^AT_EX code you inserted for typos.
2. If there are no typos, check and see that you used the command(s) correctly.
3. If you get a bunch of error boxes piled up at the very top of the document, it means that there are errors in the preamble. Start debugging your preamble.
4. If you didn't add anything to the preamble and didn't add any L^AT_EX code to the document, the first suspect is your L^AT_EX distribution itself. Check for missing packages and install them.

5. Okay, so there are no missing packages. Did you use any of the fine-tuning options in LyX? Specifically, did you *misuse* any of them, like trying to manually insert lots of Protected Blanks, Linebreaks, or Page-breaks? Did you try to kludge something together with these instead of using the appropriate paragraph environment?
6. Alright, you didn't use any of the fine-tuning options, you played by the rules. Did you try to pull a fancy manuver? Did you do something funky inside a table or an equation, like inserting a graphic into a table cell?
7. Did you go overboard with the nesting? LyX [currently] doesn't check to make sure you're in the limits for nesting environments. If you nested a bunch of environments to the 17th level, that's the problem.
8. Okay, you didn't get any error messages, but your output looks whacked. If you have a table or figure that's too wide or long for the page, you need to:
 - (a) rescale the figure so it fits.
 - (b) trim down the table so it fits.

If something else is wrong with the output, and you didn't try to pull anything fancy or kludge the fine-tuning options, we're not sure what's wrong.

If all this doesn't help — well, then *perhaps* you might have found a bug in LyX

Chapter 6

Mathematical Formulas

6.1 Basic Math Editing

Editing mathematical expressions in L_YX is now almost-completely WYSIWYM. This is something that makes many old T_EX users worried¹. They like to be able to use the keyboard to enter things like \$ α \$ (this gets, in ordinary T_EX, an α in the final document), believing that it is faster than chasing around menus for a symbol. Here's a testimonial of one of those old T_EX users, DAVID JOHNSON:

I was finally convinced that the math-editor (Mathed) was the way to go when I found that, with a few modifications, I could use it the same way I was accustomed to writing T_EX. As an example, I created this α by typing the following keys: First type M-c m to enter **math-mode**, then type `\alpha` , then Space and Esc. As soon as I typed that Space the α was right there on the screen.

The M-c m sequence starts **math-mode**, the `\alpha` is of course the standard T_EX code, and the Esc leaves **math-mode**. It is a little slower getting in to **math-mode** than with standard T_EX (for this mode, maybe, at least), but the advantages:

- You have immediate visual feedback to be sure your T_EX was correct,

¹*Author's Note: I'm one of them. - dlj*

- You have the real mathematical expression on the screen, correctly displayed, to make sure your mathematics is correct (correctly written, at least),
 - All the new L^AT_EX fuss with special environments and such are taken care of by L_YX, not you,
 - You won't have to chase through the code trying to find that missing \$ or extra { any more.
 - If you don't remember the L^AT_EX name of a particular symbol, like ϕ , you can find it in the popups.
- these advantages mean that you will be faster writing mathematics with L_YX than with raw L^AT_EX.

6.1.1 Invoking Mathed

There are several ways to invoke Mathed. You can just click on the icon with $\frac{a+b}{c}$ on it. That will open a little blue square, with a purple rectangle around it. That blue square is the math-cursor position, and the rectangle indicates that you are in math-mode. There is also a choice on the Math menu that does the same thing, or you can use a keyboard macro, A-c m. Starting Mathed in either of these ways produces an in-line Mathed box. To make it a displayed equation box, select Display from the Math menu.

If you are using math-mode to simply type, say, a Greek letter, α , there is a special shortcut, just type A-m g a to get α , A-m g b to get β , etc.

You can also invoke Mathed from the Math Panel popup, or Math Panel for short. The Math Panel is incredibly useful, so you may want to open it and leave it somewhere on the screen. Select Math Panel from the Math menu to open it. Selecting anything from the Math Panel will also start Mathed.

6.1.2 Navigating an Equation

You can click on an existing Mathed equation (anything in blue text) and you will automatically activate Mathed, and place the cursor near where you clicked. The best control over cursor position within an existing equation is achieved with the arrow keys. Mathed uses small squares to indicate places

where something can be inserted, since Mathed needs more than simple linear arrangement of symbols.

The arrow keys can be used to navigate between text areas in any Mathed structure. Pressing an arrow key when at the edge of Mathed will leave Mathed, if the arrow is pointing out of the Mathed box. Pressing Space will leave a fraction or other Mathed structure (a square root $\sqrt{2}$, or parentheses (f) , or a matrix $\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$), staying within Mathed. Pressing Esc will exit

Mathed, placing the cursor to the right of the box. Tab can be used to move horizontally in a Mathed structure, like the rows of a matrix or the positions in a multiline equation.

Space seems to do nothing in Mathed, since it does not in fact add a space between characters, but it does exit a nested structure. For that reason, you have to be careful about using Space. For example, if you want $\sqrt{2x+1}$, type `\sqrt` then Space, then `2x+1`, not `\sqrt` Space `2x` Space + Space `1`, since in the latter case only the `2x` will be under the square root sign, $\sqrt{2x} + 1$. For those who learned to space out expressions in this way, it takes a little unlearning.

Speaking of the Space bar, you may want to create blank spaces, beyond the standard spacing that L^AT_EX provides. We don't recommend this as a matter of course, since the whole idea of WYSIWYM is that you don't think about the typesetting, but the content. However, there are situations where you will want to add spaces. The first thing to do is to type C-Space. This generates a small space, and prints a small red underscore on the screen: `a b`. The next trick is to change that space to different sizes. *Before* you move the cursor, after typing C-Space, if you hit Space again, you will change the size of the space, through a number of variable sizes. The last one in the list is blue, and is a negative space. For example: `a b`, or `ab`.

L_YX complains if you leave a Mathed structure with blank insertion point, with a few exceptions. You can leave a matrix partially filled in, such as:

$$\begin{pmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_n \end{pmatrix}.$$

6.1.3 Exponents and Subscripts

You can use the **Math** menu to add in superscripts (**Exponent** on the menu) or subscripts (called **Index**), but the much easier way is to use the standard T_EX method. To get x^2 , type (in Mathed) **x^2** then **Space**. The final **Space** puts the cursor back down on the base line of the expression, instead of the superscript. If you type **x^2y**, you will get x^{2y} , to get x^2y , type **x^2** then **Space** then **y**. Subscripts are similar, to get a_1 , type (in Mathed) **a_1** then **Space**.

6.1.4 Fractions

Create a fraction with either **\frac** (in Mathed) or using the fraction icon in the **Math Panel** popup or the **Math** menu item **Fraction**. You will be presented with an empty fraction, with two Mathed insertion squares top and bottom. The cursor moves immediately to the top of the fraction. To move to the bottom, simply press **Down**. To move back up, press **Up**. Any math structure can be placed in a fraction, as this example shows:

$$\left[\frac{1}{\begin{pmatrix} 2 & 3 \\ 4 & 5 \end{pmatrix}} \right]$$

6.1.5 Sums and Integrals

Sum \sum and integral \int signs are very often decorated with one or more sets of “limits”, which are placed in L_YX (as in T_EX) as superscripts and subscripts. Sum will automatically place their “limits” over and under the symbol in **displaystyle**, but will move them to the side when inlined, such as $\sum_{n=0}^{\infty} \frac{1}{n!} = e$, versus

$$\sum_{n=1}^{\infty} \frac{x^n}{n} = \ln \left(\frac{1}{1-x} \right).$$

Integral signs, however, will not by default move the limits to directly over and under the integral sign in **displaystyle**, as in $\int_a^x f(t)dt := F(x)$, versus

$$\int_{-\infty}^{\infty} \frac{dx}{1+x^2} = \pi.$$

Both symbols will be automatically re-sized when placed in display mode. Certain other mathematical expressions have this feature as well, such as

$$\lim_{x \rightarrow \infty} f(x),$$

which will place the $x \rightarrow \infty$ underneath the “lim” in display mode, but not in inlined mode, $\lim_{x \rightarrow \infty} f(x)$.

6.1.6 The Math Panel

The **Math Panel** popup has a more extensive list of symbols and structures. As stated earlier, you can keep the **Math Panel** open when writing mathematics. That allows you to have easy access to the less trivial features of **math-mode**.

The first two icons in the **Math Panel**, as indicated, produce square root, $\sqrt{2}$, or fraction $\frac{1}{2}$ regions. The third icon, with square brackets around an insertion square, pops up the **Delimiter** popup with choices for left and right large delimiters, {3}. These will adjust to fit whatever is placed inside them. The fourth icon calls up the **Decoration** popup, which gives choices for bars, arrows, tildes and braces, placed either above or below the insertion point, \hat{V} . These also adjust to accommodate any Mathed structure. The next icon pops up the **Math space** panel, which allows the possible types of protected spaces available in math mode 2 3. Sixth is the **Matrix** popup, which has controls for the size of matrix created, as well as alignment
$$\begin{bmatrix} 1 & 2 & 3 \\ 45 & 67 & 89 \end{bmatrix}$$
.

The braces around a matrix are added using the **Delimiter** popup. The last icon, if clicked while the cursor is in text mode, creates an empty math-mode region:

$$1 + 2 = 3.$$

It will be created in display-math mode. Clicking this icon while in math-mode will toggle the math-insert between inlined and display mode.

In addition, the **Math Panel** has several submenus containing math symbols. We'll outline how to use them in the next section.

6.1.7 Other Math Symbols

Commonly-used symbols, and other menus, can be reached directly from the **Math** menu, including **Fraction**, **Square root**, **Exponent**, **Index**, **Sum**, **Integral**,

Math Mode, and Math Panel... . Most math symbols can be found in the Math Panel popup under one of several categories, Greek Γρεεκ, operators ±×, relations $\leq\cong$, arrows $\uparrow\downarrow\leftrightarrow$, large operators $\sum\int$, and the dreaded **miscellaneous**, *Misc.* If you know the standard L^AT_EX macro for a particular symbol you which to use, you do not have to use these popups, but they will help for those symbols whose L^AT_EX name you do not know. For a symbol whose L^AT_EX macro you know, all you need to do is type it, including the leading \ that L^AT_EX uses, such as in \alpha, and it will be converted automatically to the real symbol as soon as you type a Space, or other non-alphabetical symbol. The text as type it appears in red, (the \ will not appear) but will change to a blue symbol that tells you visually that LyX understands what you wanted. If Mathed is not able to convert the symbol as typed, it will remain in red (this is called *macro mode*).

Not all symbols available in L^AT_EX can (yet) be displayed WYSIWYM in LyX. If you try a symbol whose L^AT_EX name you know, like \oint for \oint , when you finish typing that string, and then hit Space (or a number, or another non-standard character), LyX will display the symbol whose macro you typed if it can. If it can't, it will leave the macro in red, such as $A \hookrightarrow B$. If L^AT_EX can handle that macro, it will print accordingly. Some of the symbols accessible from the Math Panel will display in this fashion, as will any that are defined in L^AT_EX but not yet in the LyX menus. This also allows you to define your own shortcut macros (put the command string in the preamble (see 5.4.1). For example, the string:

```
\newcommand{\a}{\alpha}
```

in the preamble will allow you to use \a in Mathed instead of \alpha to generate α . One caution, though, is that LyX will not concern itself with whether such a macro is valid, and if not you will have error messages when you try to preview or print (or run L^AT_EX). For more details, see 5.3.

There are some mathematical symbols that are not accessible from plain L^AT_EX (or LyX), but are fairly common in mathematical typesetting, such as the old-German fraktur font and the stylized “blackboard bold” fonts commonly used to denote the real or complex numbers, or the integers. In order to use these fonts, you need to add

```
\usepackage{amsmath,amsthm}
\usepackage{amsfonts}
```

to the preamble. Then you can use the standard L^AT_EX sequence within math-mode to obtain the font or symbol you need.

6.1.8 Accents

In math mode you insert accented characters in the same way as in text mode. This may depend on your keyboard, or the bindings file you use. You can also use T_EX macro equivalents, as macros. That is, you can enter \hat{a} to get the same effect if your keyboard does not have accents enabled. This is entered by typing `\hat{a}` in Mathed. These are the equivalences between the text names and math-mode names for the various accents:

text	math	example
circumflex	hat	\hat{a}
grave	grave	\grave{a}
acute	acute	\acute{a}
umlaut	ddot	\ddot{a}
tilde	tilde	\tilde{a}
dot	dot	\dot{a}
breve	breve	\breve{a}
caron	check	\check{a}
macron	bar	\bar{a}
—	vector	\vec{a}

6.2 Brackets and decorations

There are several brackets available through LyX. For most purposes, using just the keys `[{}]{()}` should suffice, but the effect, especially if you want to surround a large structure, such as a matrix or a fraction, or if you have several layers of brackets, is better using the **Math Panel's Delimiter** popup [see sec. 6.1.6]. For example, that's how you would construct the brackets around a standard matrix such as :

$$\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix},$$

and to make it easier to see the layers of parentheses of an abomination such as:

$$\frac{1}{\left(1 + \left(\frac{1}{1 + \left(\frac{1}{1+x}\right)}\right)\right)}$$

or:

$$f(g(h(k(l(x))))).$$

The parentheses, and other brackets, from that menu will automatically resize to accommodate the size of what is inside (This is done in straight L^AT_EX by `\left(blah \right)`).

If you decide after the fact to place parentheses (or other math structure, like a square root, or other decoration) around some math structure, you can do that by highlighting (selecting) the structure that is to go inside the parentheses (for now, that is done by holding the Shift key down and moving the cursor with the arrow keys). Then, choose the appropriate brackets for left and right, and click on **Apply**. The parentheses will be drawn around the selected structure.

6.3 Arrays and Multi-line Equations

Arrays, such as matrices, are easily entered in L_YX. In the Math Panel there is a **matrix** icon, which will open a popup for you to choose the number of rows/columns. Here is an example:

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}.$$

The parentheses aren't automatic, but you can add them with the **delimiter** menu. Remember that you can add this after the fact, by highlighting the matrix inside Mathed (Position the mouse on one side of the matrix, hold the Shift key down, and hit the appropriate arrow key to move the cursor across the matrix). You can, when you construct the matrix, decide whether the columns (or some of them) will be left-, right-, or center-justified. That is that panel which appears as `ccc` by default. You should be careful about determining how many rows and columns you need. You can add more rows to an existing matrix by hitting C-Enter while in the matrix, and you can

delete rows with C-k, but you can't add or delete columns, yet. Here's another example, with different alignments on the three columns:

<i>this column</i>	<i>this column has</i>	<i>this column has right .</i>
<i>has left alignment</i>	<i>center alignment</i>	<i>alignment</i>

There are numerous other arrays used in L^AT_EX math-mode, particularly with the AMS-L^AT_EX packages included, such as \cases and commutative diagrams. These are not yet supported in LyX (one such array, the \cases environment, is now supported in development versions of LyX). However, it is possible to build these structures from a matrix (which is exactly what the \cases macro is, anyway). Here is a simple example of how LyX can display cases:

$$f(x) := \begin{cases} \frac{1}{q}, & \text{if } x = \frac{p}{q} \text{ (in lowest terms)} \\ 0, & \text{if } x \text{ is irrational} \end{cases}$$

This was constructed by first choosing delimiters, where the one on the right is a blank delimiter, then choosing inside the delimiters a 2×2 matrix, with both columns left-justified. The Roman text setting will be explained later.

Multi-line equations are very easy to construct in LyX. The display-math mode of Mathed will automatically switch to an eqnarray format (L^AT_EX's multi-line displayed equation format) if, in the displayed-equation box, you hit C-Enter. The best way to do this, if you decide you want a multi-line displayed equation, is to insert a new line (with C-Enter) immediately. Each line then has three regions, left, center, and right, which you can move through using either the arrow keys, the mouse, or the Tab key. Here is an example:

$$\begin{aligned} 3 &= 1 + 2 \\ 4 + 5 &= 9. \end{aligned}$$

You can also turn an existing displayed formula into a multi-line formula by hitting C-Enter while the cursor is anywhere on the original formula. However, LyX will try to decide where to break the formula up into three parts, and chooses the first binary operation that it finds (except those inside parentheses) as the center. So, if you turn the equation:

$$3 = 1 + 2$$

into a multiline equation, the equals sign will be the center of the line, but if you split:

$$4 + 5 = 9$$

the center will be the plus sign. You then would have to edit that line, or delete it. You can delete a line of a multi-line formula by placing the cursor on the line and hitting C-k.

6.4 Equation Numbering and Labels

Equation numbering is very easy in LyX. All it takes to change a displayed equation like:

$$1 + 2 = 3$$

into the numbered equation :

$$1 + 2 = 3 \tag{6.1}$$

is to go to the **Insert** menu, and select the **Label...** option. This opens a popup in which you must enter some string as the label. There is no need to call it by a specific number, since L^AT_EX will take care of re-numbering the equation. Labels will not appear as such on the final output. L^AT_EX will insert appropriate numbers for the equations. The labels are used internally for cross-referencing. You can turn on numbering without a specific label by entering **math-number** in the minibuffer (the line below the main LyX window, which usually displays information about the document. Click on it, and the mini-buffer clears, allowing you to enter commands such as these.) while the cursor is in the equation, such as:

$$1 + 1 = 2. \tag{6.2}$$

This behaves as a toggle. Entering **math-number** in the mini-buffer a second time removes numbering. You can reference a labelled (not just numbered) equation, (cf. (6.1)) by using the **Cross-Reference** popup, which you open using **Insert->Cross-Reference...**. Note that, at the moment (version 0.10.7), you should not use spaces in your labels, since they get deleted and cross-references will no longer work. This is a bug that is fixed in development versions.

For numbered (or labelled) multi-line formulas, the default is that all lines are numbered separately. Once you attach a label to make the equation numbered, all subsequent lines receive a label of $\#$. That label can be changed to another so that you can refer to that line, like (6.5) below.

$$1 = 3 - 2 \tag{6.3}$$

$$2 = 4 - 2 \tag{6.4}$$

$$4 \leq 7. \tag{6.5}$$

You can turn off numbering of a specific line by entering `math-nonumber` in the minibuffer (below the main LyX window) while the cursor is on that line of a multi-line numbered equation. This also toggles. Though it may seem odd, entering `math-nonumber` again will turn the numbering back *on* for that line.

$$1 = 4 - 3 \tag{6.6}$$

$$2 = 7 - 5 \tag{6.7}$$

$$1 = e^{2\pi i}$$

$$16 \equiv 2 \pmod{7} \tag{6.8}$$

Note that the first equation in this set (6.6) is labelled, the next is numbered but unlabelled, the third is unnumbered, and the last (6.8) is again labelled.
[Editor's Note: For some reason, you can't use the accelerator key, M-x, to access the minibuffer while inside Mathed. If you type M-x, LyX exits math mode. So, if you want to use the minibuffer from inside Mathed, you need to click on it with the mouse. -jpw]

6.5 Fine-Tuning

6.5.1 Typefaces

You can enter various typefaces in Mathed, but (at the moment) you have to use keyboard commands to set them. Not all appear exactly WYSIWYM, and a few don't appear WYSIWYM at all. The standard font for text is italic, *text*, but for numbers the standard is Roman. To set text in Roman font in math-mode, type M-c r once in math-mode text. To get bold, **text**, type M-c b in math-mode. To get calligraphic font for capital letters (which looks

like Helvetica italics on-screen, but is fancier on the final output), $\mathcal{T}\mathcal{E}\mathcal{X}\mathcal{T}$, type M-c **i** in math-mode. Here is a table with all the supported fonts:

Text-mode	Math	Mathed Keybinding
Bold	Bold	M-c b
<i>Emphasize</i>	<i>CALLIGRAPHIC</i>	M-c e or M-c i
—	Roman	M-c r
Typewriter	Typewriter	M-c p
Default	<i>Default</i>	M-c Space

The keyboard command to switch to a particular text font is interpreted in math-mode as indicated. Math-mode does not support all characters in all fonts, and only letters will be supported with these font styles; only capital letters for calligraphic font.

For any of these fonts, you have to be careful how you enter the text. If there is text to the right of the entry point, the font reverts to that style after one character. To be able to type a string in a particular font, make sure there is a protected-space to the right of the cursor. Also, entering a protected-space will revert subsequent text to standard font.

It is possible (in AMS-L^AT_EX) to embolden (not italicize) numbers and special symbols in math-mode. However, L_YX does not yet support this in WYSIWYM. It will print correctly, though. To get emboldened symbols, for example a bold α , enter `\boldsymbol{\alpha}` in Mathed. The `\}` is needed to place that close-brace in T_EX mode. This works for all symbols, as well as numbers. It is also possible to get Fraktur fonts by entering, say, `\mathfrak{g}` for a Fraktur g , or the “blackboard-bold” double-line capitals with `\mathbb{R}`. These symbols will not appear (yet) WYSIWYM in L_YX, and the AMS-L^AT_EX packages (including amsfonts) must be used. You simply include the following lines in your preamble (see 5.4.1):

```
\usepackage{amsmath,amsthm}
\usepackage{amsfonts}
```

We do not have examples of these fonts in this Guide so that the Guide can be previewed and printed without these packages, which some people would not have available.

6.5.2 Font Sizes

There are four (relative) font sizes (or “styles”) used in math-mode, which are automatically chosen in most situations. These are called *textstyle*, *displaystyle*, *scriptstyle*, and *scriptscriptstyle*. For most characters, *textstyle* and *displaystyle* are actually the same size, but fractions, superscripts and subscripts, and certain other effects, are set larger or placed differently in *displaystyle*. Except for some operators, which re-size themselves to accommodate various situations, all text will be set if these various sizes as L^AT_EX thinks is appropriate. These choices can be over-ridden by setting the *math-size* in the minibuffer. For example, you can set $\frac{1}{2}$ normally (*textstyle*), or you can make it larger, which also changes the linespacing, in *displaystyle*, by entering *math-size displaystyle* in the minibuffer while the cursor is in the main line of the math-inset, $\frac{1}{2}$. Careful, though, if the cursor is on the denominator of that fraction, only the numerator will be enlarged, $\frac{1}{2}!$ Here are some text in the various styles: *displaystyle*, *textstyle*, *scriptstyle*, *scriptscriptstyle*.

[Editor’s Note- This isn’t working at the moment, so you won’t see any difference in the text. There is a bug in Mathed that eats the font size codes. Someday that bug will go away. -jw]

All these math-mode font sizes are relative, that is, if the whole math inset and surrounding text are set in a particular size, all these sizes will be adjusted. Similarly, if the base font size of the document is changed, all fonts will be adjusted to correspond.

Here is a paragraph in “largest” font, with symbols: α .

This also applies to math-fonts in Titles, *etc.* as well.

Chapter 7

Additional Features

7.1 Spellchecking

Editor's Note: This is highly temporary. It was taken totally from the old documentation, and needs to be completely rewritten.

Lyx itself has no integrated spell checker. However, there is a front-end for the *ispell*-program available via ftp from

- [ftp.cs.ucla.edu](ftp://ftp.cs.ucla.edu) (131.179.128.34)
- [ftp.math.orst.edu](ftp://ftp.math.orst.edu)

There are also a number of mirror sites, so check Archie first. For installation notes and where to find dictionaries, see the *ispell* documentation included with the distribution. After installing *ispell* you can use the menu entry *Spell Checker...* from the *Edit* menu card (make sure that the *ispell* binary is somewhere in your PATH).

To start spell checking, select the item *Spell Checker...* from the *Edit* menu card. Checking will start just after the current cursor position. There will appear a window showing any incorrect (or unknown) word found by *ispell* in the first line and allowing you to edit and replace it in a second line. Whenever *ispell* reports an unknown word, the word is highlighted and the view in your text buffer is updated to make the word visible. In the spell checker window, there is also a box showing “near misses”, if *ispell* can find any. Clicking to one of the near misses will copy the near miss into the replace input field (double-clicking to invoke replace is currently

not supported). The buttons in the spell checker window are quite self-explanatory: “*Accept*” accepts the word rejected by ispell and adds it to your dictionary file according to the setting of the “*Add to Dictionary*” check button. “*Replace*” replaces the word by what you have typed to the replace input field. “*Cancel*” pops up a new window asking you if you really want to cancel and performs according to your answer. Note that you can cancel spell checking at any time, not only after an incorrect word has been found. Finally, there is a slider informing you about the progress of spell checking.

There is also an item *Spell Checker Options...* on the *Options* menu card. The following options can be set (in brackets you see the corresponding ispell command line switch):

- the dictionary to be used (-d)
- whether run-together words should be treated as legal compounds (-C)
- a personal dictionary file can be specified (-p)
- a set of characters can be given which should be treated as legal characters, e.g. German umlauts (-w)
- Currently not active: Report words made from root/affix combinations (no ispell switch)

By default, the dictionary file to be used is determined by the language of the buffer to be checked. If you do not have a dictionary for the buffer language or not set any language, ispell will exit immediately after invocation. There will be a message on your stderr saying something like

```
Can't find file /usr/lib/ispell/xyz.hash
```

and a popup window will inform you about the failure. In this case, you can specify another dictionary file by clicking to the button labelled “*Use alternate dictionary*” and giving its name in the input field.

Ispell uses a personal dictionary file where words not found in the main dictionary can be saved so you don’t get the same words reported every time you check a document. The name of this file is usually formed as `$HOME/.ispell_dictionary`, where *dictionary* is the name of the global dictionary used. If you want to use another file as your personal dictionary, you can also set this in the options menu. Note that the directory in which

ispell will put your file in your home directory, not the directory the file you edit is in! Specifying a filename which does not already exist will result in an error message on stderr which you can ignore (ispell will create the file at the end of your spell checking).

7.2 International Support

[Ed. Note - This entire section is a shambles. Someone just copied stuff from the old manual and added a pithy introduction, which a)is not what I wanted; and b)I could've done that. I need to basically rewrite the whole thing or farm it out so someone else. -jpw]

7.2.1 Introduction

I think an intro to this section is a good idea; however, I'm not happy with this intro. Specifically, the user shouldn't have to talk to the local L^AT_EX guru, 'cause they may not have one! We need to provide that info. That means you need to hop on the user's and developer's lists and hunt that info down. Or you need to peruse your own trusty L^AT_EX guide. The intro should state, generically, what LyX can do in terms of internationalization support. Then, the other subsections fill in the details of that info.-jw]

Because L^AT_EX is able to support international character sets and styles LyX should also be able to do so. This means LyX should be able to display all special characters, however this is not the case at present. Nevertheless LyX is able to display all characters of the ISO8859-1 character set. It is also able to display most of the accented chars of ISO8859-2 through 4. To use these characters in your document it is quite important to have the appropriate L^AT_EX packages. With the most L^AT_EX distributions, e.g. Te_TE_X or NT_EX, you should not have to worry about international support. If you encounter problems like missing packages you will have to talk to your system administrator or to your local L^AT_EX guru. To type international characters in your LyX documents, e.g. the german umlaut (ü), it is even more important to use an appropriate *keyboard mapping* and to have your keyboard correctly set up. In the X-Window environment the latter is done with the xmodmap command, which is explained in the corresponding manual page. If you are able to type special characters in your shell or text editor you are all set and you should be able to type them in LyX as well.

7.2.2 Standard Key Maps & Usage

If you have a special, international keyboard, e.g. a german, the only thing you need to do is to set your keyboard mapping. With the current version of LyX¹ many keymaps have been supplied. There are several french and german keymaps, a turkic keymap, and many others. If you can not find what you are looking for it is generally no problem to create one for your language but you might as well ask in the users mailing list whether someone else already made one that you can use.

To change keyboard mapping to something else than a plain US keyboard, you must use Options->Keyboard. If you invoke Options->Keyboard, you will get the Keyboard Mapping dialog asking you to choose a primary and optionally a secondary language. If there is no keymap file for your language you will see an error message in the dialog box telling you:

Error: Keymap not found.

Check in \$LYXLIBDIR/kbd to see whether a keymap file is available.

If you want to activate a keyboard not listed in the pull down menu, just choose other... and type the keymap file name to use. The file will be searched in the same directories as the normal keymaps.

Now turn Mapping to either primary or secondary key map to activate the keyboard mapping. You should also set the character set to the appropriate value, i.e. iso8859-[1-4]. There is a shortcut from the keyboard to switch between keyboard mappings: Meta-K-[12otx]. As usual your options will appear in LyX mini-buffer. This feature is especially helpful if you for example need “Umlaute” from an american keyboard.

7.2.3 Dead Keys

[Rewrite this section and reorganize it. Yes, I know that many idiots have recently hopped on the user's list and whined "I can't get umlauts!" That's a clear case of DAU; ignore it. Your explanation of dead keys should be generic and should use examples from several languages, not just german. I've given you a new opening sentence. -jw]

If you're a European stuck with a US keyboard, you need to set up the so-called *dead-keys*, also called compose keys. We'll assume you've already set up X-Windows to correctly do this. If you haven't, or you need more information, look in Customization.lyx.

¹0.10.7

[Now explain what a dead key is and how it works. Oh - the abstract Key-: doesn't work. Forget the "Key" part. Example: ":" a instead of "Key-: Key-a". Keep the key names in Sans-Serif. You can put quotes - in Roman - around the whole thing if you like. Another thing to note: Some folks might have the dead-umlaut bound to the ' " ' character, so don't say that you have to use such-and-such key to produce an umlaut.-jw]

You can of course type german umlaute on a standard US keyboard by switching to an american keymap as described above. To get for example a german umlaut you will have to use a *compose key*. To get the umlaut ä type Key-: Key-a. The colon (Key-:) is the so called *compose key* or *dead key*. The dead keys of the american keyboard mapping are listed below. Note that if you really want to type the dead key symbol itself you have to type the respective key twice, i.e. type Key-: Key-: to get an :. This is of course very cumbersome so that you either will have to permanently switch between keyboard mappings (see above) or you will have to map these letters to other, seldom used keys on your keyboard.

LyX internal keybindings handle most of the dead-keys.² If this is not sufficient for you, you have to add your own bindings to .lyxrc.

If you want to be able to use all characters of the ISO8859-1 character set, you should use dead keys. The dead keys supported by X-Windows are listed below, L^AT_EX is able to support these accents as well (and adds a couple):

- dead_grave
- dead_acute
- dead_circumflex
- dead_tilde
- dead_macron
- dead_breve
- dead_abovedot
- dead_diaeresis
- dead_abovering

²Have a look at the end of keybind.C

- dead_doubleacute
- dead_caron
- dead_cedilla
- dead_ogonek
- dead_iota
- dead_voiced_sound
- semivoiced_sound

7.2.4 Using Accented Characters Directly

[Add more detail here. Explain that you need to turn on font encoding to use these, or that you need to use T1 font support. Ask on the user's list or developer's list about the details of this.-jw]

Here is a table with all the characters in the latin-1 characterset. You should be able to print all these characters directly from the keyboard without using too many modifier keys, [if your keyboard is set up correctly, that is].

	00	10	20	30	40	50	60	70	80	90	A0	B0	C0	D0	E0	F0
00				0	@	P	,	p			°	À	Ð	à	ð	
01			!	1	A	Q	a	q			í	±	Á	Ñ	á	ñ
02			"	2	B	R	b	r			g	²	Â	Ò	â	ò
03			#	3	C	S	c	s			£	³	Ã	Ó	ã	ó
04			\$	4	D	T	d	t			œ	'	Ä	Ô	ä	ö
05			%	5	E	U	e	u			¥	µ	Å	Õ	å	õ
06			&	6	F	V	f	v			—	¶	Æ	Ö	æ	ö
07			'	7	G	W	g	w			§	·	Ç	×	ç	÷
08			(8	H	X	h	x			“	,	È	Ø	è	ø
09)	9	I	Y	i	y			(C)	¹	É	Ù	é	ù
0A			*	:	J	Z	j	z			a	º	Ê	Ú	ê	ú
0B			+	;	K	[k	{			«	»	Ë	Û	ë	û
0C			,	<	L	\	l				¬	¹/₄	Ì	Ü	ì	ü
0D			-	=	M]	m	}			—	¹/₂	Í	Ý	í	ý
0E			.	>	N	^	n	~			(R)	³/₄	Î	Þ	î	þ
0F			/	?	O	—	o				—	¸	Ï	ß	ï	ÿ

The following is a full list of all of the accented characters LyX can display directly. It includes not only the accented characters from the previous table, but also the characters from ISO8859–2 through 4.

- From ISO8859–1:

“ Ä	” È	„ Í	Ö	Ü	à	ë	í	ö	ü	ÿ						diaeresis
^ Á	^ É	^ Î	^ Ó	^ Ü	á	é	í	ó	ü							circumflex
‘ À	‘ È	‘ Ì	‘ Ò	‘ Ù	à	è	ì	ò	ù							grave
’ Á	’ È	’ Í	’ Ó	’ Ú	á	é	í	ó	ú	ý						acute
˜ Ä	˜ È	˜ Í	˜ Ó	˜ Ü	˜ à	˜ è	˜ í	˜ ó	˜ ü							tilde
„ Ç																cedilla
—																macron ³

³The dead macron is usually not needed, as you will use a non-dead key for this instead.
ex. S-M-minus, or if .Xmodmap is correct S-M-macron.

- From ISO8859–2 through 4:

\hat{H}	\hat{h}	\hat{C}	\hat{G}	\hat{S}	\hat{c}	\hat{g}	$\hat{}$	circumflex	
\acute{S}	\acute{s}	\acute{R}	\acute{L}	\acute{C}	\acute{N}	\acute{r}	\acute{l}	acute	
\tilde{I}	\tilde{i}	\tilde{U}	\tilde{u}					tilde	
\S	\S	\T	\T	\R	\R	\L	\L	cedilla ⁴	
\bar{E}	\bar{e}	\bar{A}	\bar{I}	\bar{O}	\bar{U}	\bar{a}	\bar{i}	\bar{o}	macron
\ddot{O}	\ddot{U}	\ddot{o}	\ddot{u}						hungarian umlaut

[You should rewrite this paragraph and add information about what font encoding you need to set in order to make sure you can output all of these characters. That includes changing the correct widget in the Document Layout popup.-jw]

All the characters above are actively supported by \TeX fonts, in addition \TeX allows diacritical marks on almost all characters (put an cedilla under an H if you want, it will not look nice, but it is possible.) This is also supported in \LaTeX , just have to enable Options-> \LaTeX ->Allow accents on all chars. Also make sure you're using the T1 font-encoding and have the package `umlaute.sty` with the definition file `iso.def` installed.

7.2.5 Babel Support

[What is it? How do you activate it? What can it do for you? Fill all of that in.-jw]

⁴These characters might not look very nice on screen, but they will be just fine when run through \LaTeX and printed.

Chapter 8

The Dreaded Miscellaneous

8.1 Stuff We Don't Know Where Else to Put!

All of this is useful info that *was* in the old version of this doc, and should go someplace in here. We don't know where yet, so for now, it all got stuck in this section.

8.1.1 Creating an Appendix

Currently, LyX cannot display an appendix. You can use inserted L^AT_EX code to create an appendix, however. Simply insert a paragraph (with *Standard* layout) *before* the text of the appendix, with the following L^AT_EX-Command:

\appendix

Don't forget to mark the command as L^AT_EX. The headings and text following this paragraph will appear in the previewed or printed document as an appendix.

8.1.2 Other stuff

Language: The language for the babel system. This will set a few typographic switches for this language and, what is most important, will print the generated words like “Contents” or “Chapter” in the specified language. Note that LyX will not display that on the screen, but it will appear in the printed document.

PostScript: You can switch off this L^AT_EX style (`epsfig.sty`) if you do not

need it. This will make the L^AT_EX compilation faster. You need it only, if you like to include PostScript figures within your document.

Inputencoding: Choose the inputencoding you need. This will call `inputenc.sty` with the option that you choose.

Credits

The documentation is something of an exercise in stone-soup. There are lots of hands that have contributed something to the pot.

First, we need to give due credit to those who came before us. They gave us the base upon which the new manuals are built, and some continue to provide information:

- MATTHIAS ETTRICH wrote the original documentation, from which this manual is built, as well as the introduction to this manual [or the “LyX Manifesto,” as some of us call it].
 - LARS GULLIK BJØNNES wrote several minidocs, including some of the information about international support in LyX.
 - IVAN SCHRETER also wrote a minidoc about international support, specifically about international keyboard maps and customization.
 - PASCAL ANDRÉ originally documented the LinuxDoc SGML interface.
 - ALEJANDRO AGUILAR SIERRA originally documented math mode and provided the entries for the math functions in `Reference.lyx`
 - Special thanks to the LyX Team[1] for help and answers to questions.

That said, it’s time to give credit to the current LyX Documentation Team:

- DAVID JOHNSON:
 - Contributor to the FAQ and `HowDoI-.lyx`
 - General editing assistance.

- Documentation of math mode in `UserGuide.lyx`
- RICH FIELDS:
 - Primary contributor to `Reference.lyx`
 - Documentation of the basic LYX interface in `UserGuide.lyx`
- PAUL EVANS:
 - Contributor to FAQ and `HowDoI-.lyx`
 - Documentation of LinuxDoc in `UserGuide.`
- ???:
 - Documentation of:
 - * spellchecking
 - * tables
 - * figures and imported graphics

...in `UserGuide.lyx`

[Expected soon]
- ROBIN SOCHA:
 - Documentation of:
 - * footnotes
 - * margin notes
 - * table of contents
 - * cross-references

...in `UserGuide.lyx`
- MATTHIAS ZENKER:
 - Documentation of
 - * manual fine-tuning
 - * using L^AT_EX from within LYX

...in `UserGuide.1yx`

- JOHN WEISS:
 - General organization and format of the documents.
 - Documentation of
 - * LYX setup
 - * Paragraph environments, document layout, and other basic usage
 - ...with some minor changes to MATTHIAS ETTRICH's introduction section in `UserGuide.1yx`.
 - Also responsible for `Tutorial.1yx`
- Editor of the documents. [from 6/96-present]
